## Abstract

This two-part report provides an essentially complete listing of radioactive occurrences in Colorado, with a comprehensive bibliography and bibliographic cross-indexes. Part 1 lists approximately 3000 known radioactive occurrences with their locations and brief accounts of the geology, mineralogy, radioactivity, host rock, production data, and source of data for each. The occurrences are classified by host rock and plotted on U.S. Geological Survey 1° x 2° topographic quadrangle maps with a special 1:100,000-scale base map for the Uravan mineral belt. Part 2 contains the bibliography of approximately 2500 citations on radioactive mineral occurrences in the state, with cross-indexes by county, host rock, and the special categories of "Front Range", "Colorado Plateau", and "thorium". The term "occurrence" as used in this report is defined as any site where the concentration of uranium or thorium is at least 0.01 percent or where the range of radioactivity is greater than twice the background radioactivity. All citations and occurrence data are stored on computer diskettes for easy retrieval, correction, and updating.

The U.S. Geological Survey and the U.S. Department of Energy provided the largest volumes of both bibliographic and occurrence data. Additional sources included private mining and exploration companies working in Colorado, State agencies, and various published and unpublished reports.

The intimate association of radium, uranium, and vanadium on the Colorado Plateau sparked several periods of exploration that ultimately led to a mining "boom" in the 1950's. Since its meager start at Roc Creek in 1881, the Uravan mineral belt in southwestern Colorado has yielded more than 364 million pounds of  $V_2O_5$  and nearly 85 million pounds of  $U_3O_8$ .

Sedimentary uranium-vanadium ores, principally uraninite and carnotite, occur in sandstones of the Salt Wash Member of the Morrison Formation. Uraniferous vanadium is found in roscoelite deposits in the Entrada Sandstone. Uranium has also been discovered in Tertiary conglomerates in the Tallahassee Creek district in Fremont County. Uranium, recoverable by solution mining of Upper Cretaceous sandstones, is now being evaluated in Weld County. Vein-type uranium occurrences are typified in Jefferson County by the Schwartzwalder Mine, the largest uranium mine in Colorado.

Since its use in the atomic bomb, uranium has become more important as a nuclear reactor fuel and as an alloy in aerospace and metallurgical applications. Another potential reactor fuel is thorium, which is found both in fossil beach-sand placers and in veins. It too has metallurgical, chemical and industrial applications.

## Introduction

The primary objective of this report is to provide in one document as complete a listing as possible of all radioactive occurrences in Colorado with a cross-indexed bibliography. This publication summarizes widely scattered data, much of which had been classified or was not generally available to the public. The report, therefore, should be invaluable to government agencies for planning and impact studies, and to geologists, explorationists, industry, students, landowners, and developers, and all citizens of the state. We believe it is the most comprehensive and complete report of its kind for Colorado.

This project, funded by the Grand Junction Office of the Department of Energy (DOE) under Contract EY-76-C-13-1674, is presented in two parts. Part 1 lists all known radioactive occurrences with their locations and a brief account of the geology, mineralogy, radioactivity, host rock, production data and source of data. The occurrences are plotted on U.S. Geological Survey 1° x 2° topographic quadrangle maps (scale 1:250,000), with a separate 1:100,000-scale base map for the Uravan mineral belt. Part 2 includes the bibliography of literature on radioactive mineral occurrences in the state with cross-indexes by county, host rock, and the special categories of "Front Range", "Colorado Plateau", and "thorium".

A customized computer program was developed to handle the occurrence and bibliographic data as it was gathered. This made possible the retrieval of a wide variety of types of data by county or area, or the creation of cross-indexes of bibliographic or subject data.

The bibliography drew references from many sources, with the beginning base being the GEOREF bibliography for Colorado (Colorado Geological Survey Bulletin 37) prepared for the Colorado Geological Survey by the American Geological Institute. Additional reference lists from the U.S. Geological Survey, U.S. Atomic Energy Commission, U.S. Energy Research and Development Administration, U.S. Department of Energy, and other published and unpublished sources were incorporated into the bibliography. The bibliography was assembled with keywords so that cross-indexes by county, host rock, "Front Range", "Colorado Plateau", and "thorium" could be pulled from the computer storage and printed separately.

The authors visited most of the major deposits and at least one of each type of occurrence in the state. The term "occurrence", as used in this report is defined as being any site or area where the concentration of uranium or thorium is 0.01 percent or greater or where the range of radioactivity is greater than two times the background radioactivity. Because of the numerous occurrences and the relatively short term of the project, no attempt was made to visit all occurrences--in fact, it would have been physically impossible. Appropriate notation is made when an occurrence could not be adequately verified.

## HISTORY AND BACKGROUND

The development of uranium mining in Colorado reflects the natural association, development of knowledge, and demand through the years for three metals: radium, vanadium and uranium. Uranium was first discovered in the United States in 1871 at the Wood Mine in the Central City district (Sims and others, 1963, p. 5). It became important because of its association with radium, which was in great demand as a result of the work of Marie and Pierre Curie. Production from the Central City district totalled about 36 tons of  $U_3O_8$  by 1900 and most of that was hand-sorted high-grade ore. In the Roc Creek area of Montrose County uranium ore (containing radium) was discovered in 1881. From this district, 10 tons of carnotite ore was mined and shipped to Marie and Pierre Curie in 1898. This small Roc Creek district was the beginning of the Uravan mineral belt, the largest uranium-producing area in Colorado today.

Colorado ranks fourth among the states in production of uranium and first in production of vanadium recovered from sandstone uranium ores. The table below summarizes salient statistics on uranium and vanadium produced and recovered from 1948 to January 1, 1978. The majority of that production was from sandstones, but production figures from other types of deposits are also included.

The first two producing districts mentioned above, the Central City (Front Range) area and the Uravan mineral belt, represent the two major, geologically distinct, uranium-producing areas in Colorado (Fig. 1).

TABLE 1  
Uranium and vanadium produced in Colorado  
1948 to January 1, 1978

	<u>Tons of ore</u>	<u>Pounds recovered</u>	<u>Grade %</u>	<u>% US total</u>
Uranium ( $U_3O_8$ )	17,260,000	84,832,300	0.25	13.45
Vanadium ( $V_2O_5$ )	15,834,900*	364,275,400	1.15	74.18

\*This tonnage of ore is included in the tons of uranium ore.

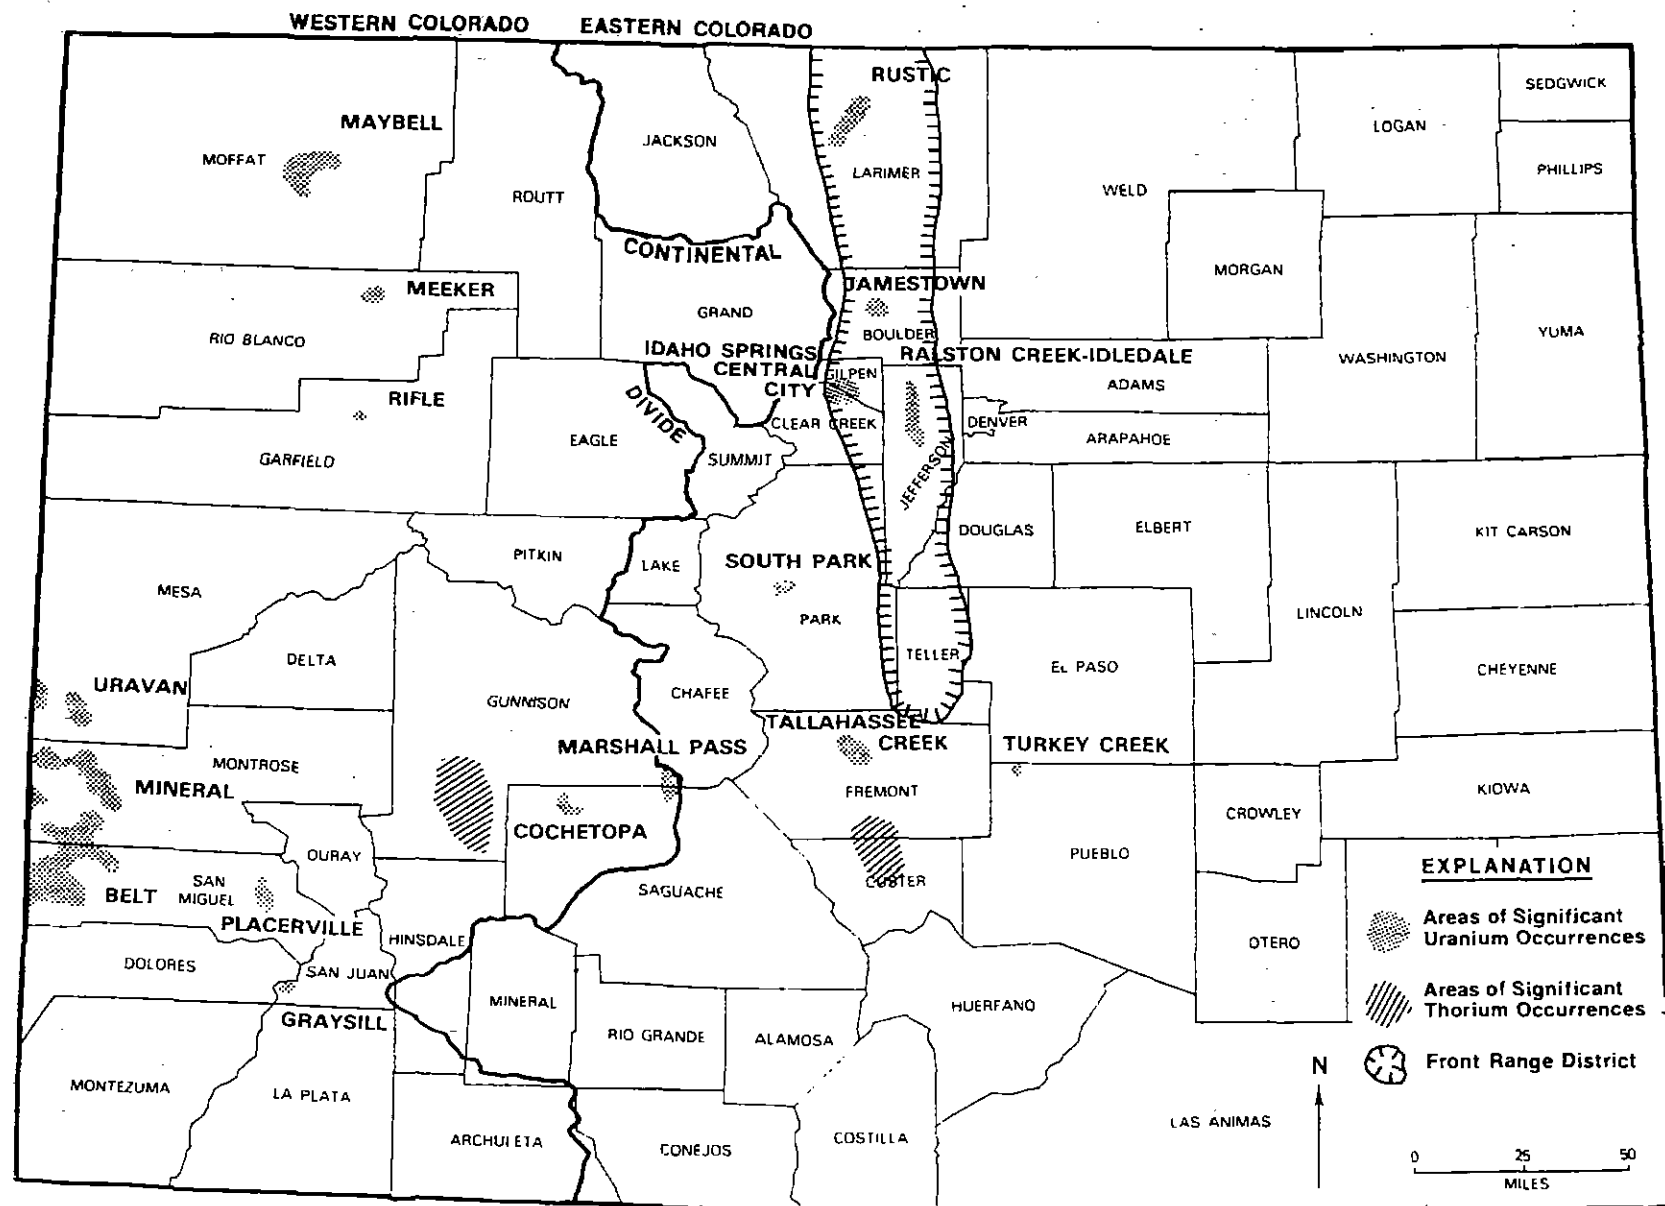

Figure 1. Uranium and Thorium Districts in Colorado (After Morse, J.G., and Curtin, M.S., 1977, Colorado Energy Resources Handbook, Volume 3 - Uranium: Colorado School of Mines, Golden, Colorado.)

System or series	Group	Formation	Member or tongue	Thickness (feet)	Description	Direction of sediment transport
Upper and Lower(?) Cretaceous		Dakota		0-200	Sandstone and shale, gray and brown; cliff-forming, widespread	
Lower Cretaceous		Burro Canyon		0-250	Sandstone, light-colored, conglomeratic, and green and maroon mudstone; mesa capping; absent in western part of area.	
Upper Jurassic		Morrison	Brushy Basin	300-500	Shale (or mudstone), varicolored, some sandstone lenses; forms slopes; widespread.	Northeast
			Wentwater Canyon	0-350	Sandstone, light-colored; forms cliffs and benches; absent in northern part of area.	Northeast
			Recapture	0-080	Shales, red, and sandstones; forms cliffs and benches; absent in northern part of area.	Northeast
			Salt Wash	0-400	Sandstone, light-colored, and red mudstone; forms cliffs and benches; widespread.	Northeast
	San Rafael		Bluff	0-55	Sandstone, red, massive; forms cliff; absent in northern part of area.	
			Summerville	0-400	Shale, red and gray, and thin sandstone; forms slopes; thickens westward; widespread.	
			Curts	0-100	Sandstone, light-colored; absent in southern Utah.	
			Entrada	50-1,000	Sandstone, light-colored; forms cliff; thickens westward to red earthy sandstone.	
Upper and Middle Jurassic		Carmel		0-600	Sandstone, red, earthy; thickens westward to gray and red shale, limestone, and gypsum; widespread.	
Jurassic and Jurassic(?)	Glen Canyon		Navajo	0-2,000	Sandstone, red; irregularly bedded; forms bench; absent in eastern part of area.	Southeast
Jurassic(?)			Kayenta	0-300	Sandstone, light-colored, massive; cliff-forming; absent in western Colorado.	
Upper Triassic			Wingate	0-100	Sandstone, red, massive; cliff-forming; absent in eastern part of area.	Southeast
		Chinle	"A" unit of Gregory	0-350	Siltstone, red, and sandstone; forms ledges and slopes; widespread.	
			Owl Rock	0-450	Limestone, gray, and red siltstone; forms ledges and slopes; widespread.	
			Petrified Forest	0-700	Claystone, variegated; forms slopes; widespread; absent in northern Utah.	
			Moss Back sandstone	0-150	Sandstone, light-colored, conglomeratic; cliff-forming; fills channels; widespread.	Northwest
			Monitor Butte	0-250	Claystone, gray, and sandstone; forms slopes; widespread.	
		Shinarump		0-250	Sandstone, light-colored, conglomeratic; cliff-forming; fills channels; widespread.	Northwest
Middle(?) and Lower Triassic		Moenkopi	Shubad	0-700	Siltstone, red, and sandstone; contains ripple marks; forms slopes and ledges; widespread.	
				0-200	Limestone; absent in eastern part of area.	Northwest
				0-200	Siltstone, red; contains ripple marks; forms slopes and ledges; thins eastward.	
Permian		Kaibab	Hoskinsburg	0-120	Siltstone, red; absent in northwestern part of area; forms steep slopes and cliffs.	
			White Rim	0-230	Sandstone, white; cliff-forming; absent in eastern part of area.	
	Coconino	Cutler	De Chelly	0-860	Sandstone, light-colored; cliff-forming; absent in northern part of area.	Southwest
			Organ Rock	250-800	Siltstone, red; forms steep slopes; absent in northern part of area.	
			Cedar Mesa	0-1,250	Sandstone, light-colored; thickens northward; forms cliffs and benches.	Southeast
			Holgalto	0-500	Siltstone, red, and sandstone; absent in northern part of area.	
Permian(?) and Pennsylvanian.		Rico		300-500	Sandstone, red, siltstone, and light-gray limestone; forms cliffs and ledges; widespread.	

Figure 2. Generalized Stratigraphy in the Uravan mineral belt area (from Pool and Williams, 1956.)

## GEOLOGY OF COLORADO URANIUM DISTRICTS

Western Colorado (Fig. 1), lying west of the Continental Divide, is the site of the oldest uranium mining area in the United States. The Uravan mineral belt, as it is known, is an arcuate belt extending from western Montrose and San Miguel Counties through southwestern Mesa County and into eastern Utah. It produces vanadium-uranium ores contained in sandstones--predominantly the Salt Wash Member of the Morrison Formation (Fig. 2).

Ore bodies are contained in continental sandstones with the mineralized rock forming elongate podlike masses and irregular bodies called "rolls". Roll ore deposits lie generally near the base of thick sandstone units where thin but well-defined mudstones are interbedded with thin sandstones (D. R. Shawe, 1956). Rolls commonly show C, S, and socket shapes in cross section but may be complicated by splits, bulges, loops, flattening or transition into tabular deposits (Fig. 3).

Figure 3. Cross-sections of Uranium Roll Fronts (From Shawe, 1956).

Minor elements are usually asymmetrically distributed across an ore body (Fig. 4). In the Salt Wash Member of the Morrison Formation, layers rich in hematite or limonite, calcite, and selenium are commonly found concentrically arranged on the

concave side of roll ore deposits. Where numerous and well developed deposits tend to lie in clusters, generally elongated in a common direction nearly perpendicular to the trend of the belt. Ore in these deposits may range in size from less than a ton to several hundred thousand tons. The grade ranges from a trace to several percent uranium oxide ( $U_3O_8$ ), generally averaging 0.2 to 0.3 percent  $U_3O_8$ .

Figure 4. Mineral Distribution of Roll Fronts (From Shawe, 1956).

The Uravan mineral belt contains about 1200 mines, some active and many inactive. Since 1948 the Colorado portion of the belt has produced 12,742,000 tons of ore averaging 0.25 percent  $U_3O_8$  and containing 63,336,400 lb of uranium oxide ( $U_3O_8$ ) with 331,778,000 lb of vanadium oxide ( $V_2O_5$ ) recovered as a co-product. The average uranium-vanadium ratio has been about 1:5, but it varies considerably. This production from the Uravan mineral belt represents 89 percent of the total uranium production in western Colorado.

Other deposits of the type found in the Uravan mineral belt occur in the Salt Wash Member of the Morrison Formation on Coal Creek Anticline east of Meeker in Rio Blanco County.

Large uraniferous vanadium deposits occur in the Entrada Sandstone northeast of Rifle in Garfield County, near Placerville in San Miguel County, and

north of Graysill Mountain in San Juan County. Smaller similar types of deposits occur in the Lightner Creek area in La Plata County. Some ore also occurs in the Jurassic (?) Navajo Sandstone at Rifle. These uraniumiferous vanadium deposits are referred to as the "roscoelite-type" because of the vanadium mica that is always associated with them. This belt appears to be continuous from the La Plata Mountains to the area near Rifle.

Another uranium mining district is found near Maybell on the south flank of the Sand Wash Basin in Moffat County. There, the Browns Park Formation, a fluvial, arkosic, locally tuffaceous sandstone of Miocene age serves as the host for uranium deposits. These deposits are roughly tabular, consisting of groups of lenticular, discontinuous ore bodies distributed within a limited stratigraphic interval. Relatively large amounts of low-grade ore occur in the upper part of the Browns Park Formation. Currently, Union Carbide Corporation is producing approximately 200,000 lb of  $U_3O_8$  annually from this locality by a heap leach method.

Vein-type deposits in western Colorado are subordinate in size and numbers to those deposits in sandstone but are represented by two significant areas. Marshall Pass, the first area, straddles the Gunnison-Saguache County line just west of the Continental Divide. Geologically, it consists of an exposed remnant of Paleozoic rocks bounded on the east by the Chester Fault, a high-angle reverse fault. Precambrian granites, schist and gneiss from the east were pushed over these Paleozoic rocks. Ore bodies at the Pitch Mine, the largest uranium producer in the area, consist of numerous pods and lenses in brecciated, steeply dipping limestones and dolomites in the Belden Formation, in the hanging wall of the Chester Fault. The surface trace of the fault is undulatory, but strikes generally in a north-south direction. The eastward dip varies from about  $40^\circ$  to nearly vertical. Displacement is believed to be at least 1,400 ft and possibly as much as 2,000 ft. Uraninite is the primary ore mineral. Development is currently under way to bring this mine back into production.

The Cochetopa district, the second principal area of vein-type deposits in western Colorado, is located on the northern margin of the San Juan Mountains and was discovered in 1954. The deposits in the area consist of nearly vertical tabular bodies in brecciated and silicified Morrison sandstone and siltstone along the east-west-trending Los Ochos high-angle, normal fault. The principal ore is uraninite.

Small amounts of uranium have been produced in western Colorado from numerous localities outside these major areas in a variety of sedimentary, metamorphic and igneous host rocks. Production from all western Colorado areas, exclusive of the Uravan mineral belt, totals 2,847,100 tons of uranium ore, yielding approximately 7,806,000 lb of  $U_3O_8$  with an average grade of 0.137 percent  $U_3O_8$ . The total production for western Colorado is 15,589,000 tons of ore yielding 71,132,400 lb of  $U_3O_8$  (Table 2, Chenoweth, 1977).

The second major producing area in the state is the Eastern Slope, defined very broadly as all of the area between the Continental Divide and the Great Plains (Fig. 1). The major districts within the Eastern Slope are the Front Range district and the Tallahassee Creek district. In general, less is known about uranium resources in the Eastern Slope than in western Colorado, simply because there has not been as much interest in exploring for Eastern Slope deposits until recently. This is because uranium ores from sandstone-type deposits have produced about 95 percent of all the uranium found in the United States.

Large areas of sandstone-type deposits such as the Uravan mineral belt, the Grants mineral belt in New Mexico, and the Powder River Basin in Wyoming have been explored and mined intensively for the past 25 years. The fact that such a large proportion of mined uranium has come from sandstone, combined with the ease of exploration and mining, and the generally conservative nature of mining companies have all made sandstone-type deposits the most sought after. Consequently, exploration for uranium in other geologic environments such as the Front Range has been minimal. Today, however, more time is being spent examining "other" geologic environments for possible uranium resources. This has caused more activity in relatively unexplored areas of the state and on the Eastern Slope.

To date, most uranium in the Eastern Slope has been produced from veins of pitchblende found in small bodies associated with sulfide minerals. In most of the occurrences the veins have been mined chiefly for their precious- or base-metal content. The discovery and importance of uranium in the veins was secondary.

The Schwartzwalder Mine, about 8 miles northwest of Golden in Jefferson County, is the largest uranium mine in Colorado, and the most notable exception to the statement that uranium is secondary to base and precious metals. The Schwartzwalder produced approximately one-seventh of the total amount of uranium in the state in 1977. Total production for the mine to May 1978 is reported as 10,500,000 lb of  $U_3O_8$  (Cotter Corp., personal comm., 1978). The uranium is found in pitchblende and uraninite within veins and breccia fillings along a major fault system in Precambrian metamorphic rocks. Uranium, the major element found, has some associated copper mineralization. The Schwartzwalder Mine typifies the major type of uranium occurrence that is being sought in the Front Range district. This mine is a prime example of vein-type uranium deposits in North America.

The Tallahassee Creek area contains different types of deposits than those generally found on the Eastern Slope. There the uranium occurs in Eocene and Oligocene conglomerates, deposited primarily in ancient stream channels totally different from present drainage systems. Reports in the news media indicate that the Tallahassee Creek has more than 30,000,000 lb of recoverable  $U_3O_8$  at Cyprus Mines' newly discovered Hanson ore body. Uraninite is the principal ore mineral.

A similar but smaller deposit in High Park has a pilot open pit from which ore was graded and stockpiled for various testing purposes. This deposit will probably be worked simultaneously with the Tallahassee Creek deposit to provide supplemental feed to a new mill that is being planned near that site.

On the eastern Great Plains one other important district lies in Weld County. One important deposit here, the Grover deposit, is being developed for production. The Grover uranium deposits in Weld County, 3 miles southwest of Grover, were discovered in 1970. Uranium occurs in sandstones of the upper Fox Hills and Laramie Formations. Deposits in these formations, although generally small and low grade, contain reserves varying from a few thousand to 1,000,000 lb  $U_3O_8$  and have become commercially significant due to price increases for uranium. The average grade of the Grover Deposit is estimated at 0.14 percent  $U_3O_8$  for a 1,000,000 lb ore body (H. L. Reade, Jr., 1976). Exploration and in-situ development (Fig. 5) of these deposits are joint ventures of Wyoming Mineral Corporation and Power Resources Corporation. They conducted extensive pilot and monitoring studies and are presently planning a commercial recovery operation.

These deposits are very similar to those found along the Gulf Coast in Texas. Mining is to be carried out by the in-situ leach-mining method, which was developed for the Texas uranium deposits. The development of these deposits will make this area an important new uranium district in Colorado.

Figure 5. Diagram of In-situ Solution Mining. (From Morse, J. G., and Curtin, M.S., 1977, Colorado Energy Resources Handbook, Volume 3 - Uranium: Colorado School of Mines, Golden, Colorado, p. 19).

#### CHEMISTRY AND MINERALOGY OF URANIUM AND THORIUM

The three naturally occurring radioactive elements are potassium, uranium, and thorium, but radioactive potassium is not found in significant concentrations in the earth's crust and is not commercially important. Uranium is one of the less common elements, averaging about 2 ppm in the earth's crust. Thorium, on the other hand, is more widely distributed, usually associated with uranium or rare-earth elements, and averages about 6.5 ppm in the earth's crust.

Uranium is a polyvalent element with values of +3, +4, and +6. The hexavalent (+6) form is one of the more common forms and is soluble in both dilute acid and dilute basic solutions. Four probable naturally occurring oxides,  $UO$ ,  $UO_2$ ,  $U_3O_8$ , and  $UO_3$  are known, but pure  $UO$  is definitely established only as a thin surface layer on the native metal, which does not occur naturally.  $U_3O_8$ , an olive-green uranium-uranyl oxide, contains 84.8 percent uranium. It is used as a unit of measurement when uranium content is discussed.

"Yellowcake" is the concentrate produced at mills and is generally considered to be ammonium diuranate,  $(NH_4)_2(U_2O_7)$ , or sodium diuranate,  $(Na_2U_2O_7)$ . The exact composition depends on the conditions of precipitation. Refinery specifications, first established by the Atomic Energy Commission, require a minimum of 75 percent  $U_3O_8$  in yellowcake.

The most common uranium mineral is uraninite  $[(U^{4+}_{1-x}, U^{6+}_x)O_{2+x}]$  or  $(U^{4+}, U^{6+})U_{2.6}$ . Uraninite is a primary mineral of uranium found throughout the world and is concentrated in sedimentary deposits, granitic rocks, pegmatites and in primary vein deposits. It is commonly referred to as "pitchblende", a term that has had many meanings but is currently used to describe the sooty, fine-grained, colloform variety of uraninite.

The uranium silicate, coffinite, occurs in unoxidized sedimentary ores of the western states. Secondary (oxidized) uranium minerals include an assortment of hydrated oxides, sulfates, phosphates, vanadates, silicates, and carbonates. Carnotite, a hydrated potassium uranium vanadate, is perhaps the best known secondary uranium mineral. The term "carnotite" is often used to include any of a number of similar yellow-colored minerals, including tyuyamunite and meta-tyuyamunite.

Uranium is frequently a minor constituent of such complex oxides as uranothorianite and the fergusonite-formanite, samarskite-yttrotantalite, and euxenite-polycrase series. These contain such elements as thorium, the rare earths, columbium, and tantalum. Quadrivalent uranium is isomorphous with thorium, zirconium, and the rare-earth elements.

Most of the uranium ores in Colorado, represented by the deposits in the Uravan mineral belt and Tallahassee Creek area, occur in sandstones and conglomerates. Tyuyamunite and uraninite, the most important uranium ore minerals, occur as interstitial fillings, grain coatings, and replacements of organic or carbonaceous materials within these deposits. The ore bodies are in irregularly shaped tabular, lenticular, or roll-type deposits. Important vein-type uranium deposits are represented by the Schwartzwalder and Pitch mines, in which pitchblende is the important ore mineral.

Monazite concentrations occurring in paleo-placer beach sands and containing  $ThO_2$  are the principal sources of thorium in the world. Additional sources of thorium include veins and deposits in sedimentary

rocks (conglomerates or quartzites enriched in thorium, and uranium). Thorite ( $\text{ThO}_2$ ), thorianite ( $\text{ThSiO}_4$ ), and monazite ( $(\text{Ce}, \text{La}, \text{Y}, \text{Th})\text{PO}_4$ ), are the main thorium-bearing minerals.

Vein-type deposits are the most important sources of thorium in Colorado. Thorium, principally in the form of thorite, occurs both in the Powderhorn district in southern Gunnison County near Lake City, and in the Wet Mountain district in Fremont and Custer Counties. Uranium is associated with the thorium in these areas but only as a minor element. The occurrences are in Tertiary veins that cut Precambrian gneisses, and ultrabasic rocks. These veins are not closely associated with any recognized intrusives. Paleo-placer beach sands are found in small deposits in Elbert, La Plata, and Montezuma counties. Their potential for development is not as favorable as that of vein-type occurrences.

#### USES AND TECHNOLOGY

Uranium became important during World War II when it was used in the development of the atomic bomb. Development of uranium resources after the war became the responsibility of the U.S. Atomic Energy Commission (AEC), who required large quantities of uranium for its weapons and for nuclear research and development programs. During this time a commercial nuclear power industry, using uranium as a fuel, has slowly developed into the principal civilian use for uranium. Small amounts are also needed for medical research and other technology.

Uranium is also useful after it has been depleted in the fissionable isotope and subsequently not suitable for nuclear use. It is one of the most dense metals that will alloy readily with other metals. Through alloying it forms stable compounds that are easily fabricated and useful in numerous specialized nonenergy applications. Depleted uranium is better than lead and other less costly dense metals for gamma-ray and X-ray shielding and for containers for radioactive materials. The density and ease of fabrication make depleted uranium castings suitable for missile ballast, for control surface balancing and counterweights in aircraft and space vehicles, and for payload simulation in test space vehicles. The structural and mechanical properties of depleted uranium make it particularly useful in alloys with molybdenum and titanium for a wide range of military applications--equipment parts, ammunition and special-purpose artillery shells.

Early uses of uranium are still important and include a uranium-antimony oxide catalyst used in the plastics industry to produce acrylonitrile, a colorant in glass and ceramics, and in steel and nonferrous metallurgy. It is important in the electrical industry where it is used for targets in X-ray tubes, for electrodes in ultraviolet lights, and for resistors in incandescent lamps.

Thorium is used principally for making compounds of oxides, nitrates, and chlorides. The main nonenergy use is in the fabrication of incandescent gas mantles. Varying percentages of thorium in magnesium-base alloys are used for aircraft and aerospace applications. Small quantities are used to produce certain

high-strength, corrosion-resistant metals. Thorium oxide is the most stable of the refractory oxides but is expensive and has poor resistance to shock. Both the metal and the oxide are used in radiation detectors, electric discharge tubes, and computers.

The use of high-temperature gas-cooled reactors (HTGR), such as the one at Fort St. Vrain, would create a substantial market for thorium. These types of reactors use thorium and uranium in the feedstock. The fuel elements consist of thorium and uranium carbide-coated ceramic particles. In the fuel cycle, highly enriched  $\text{U}_{235}$  serves as the initial and make-up fissile material,  $\text{Th}_{232}$  as the fertile material, and  $\text{U}_{233}$  as the converted material.

Theoretical studies of the light-water breeder-reactor (LWBR) program will use the pressurized-water reactor (PWR) to convert  $\text{Th}_{232}$  to fissionable  $\text{U}_{233}$ . This system, under development by Westinghouse, uses thorium as the major fuel component. If successful, it would permit conversion of PWR's to LWBR cores without extensive or costly changes. Utilizing thorium as the principal fuel component would drastically reduce the increasing demand for dwindling uranium resources.

Much research is directed toward large-scale production of thorium as a nuclear fuel. Standardization of HTGR parts to speed licensing, and the development of HTGR gas-turbine powerplants could eliminate conventional steam systems. The symbiotic relationship between the gas-cooled fast-breeder reactor (GCFR) and the HTGR is an important factor in the conversion to thorium fuels, as the GCFR breeds  $\text{U}_{233}$  from  $\text{Th}_{232}$ , with the  $\text{U}_{233}$  then used to fuel the HTGR. Possible applications of heat resulting from the high operating temperature of the HTGR include coal gasification, oil production from oil shales and tar sands, and hydrogen generation (water splitting).

#### CONCLUDING REMARKS

The prime objective of this project was to compile a reference data base for uranium and thorium exploration, for land-use planning and impact studies by government agencies, and as general information on radioactive occurrences for students, landowners, developers, and all citizens of the state.

Every effort has been made to ensure that the report is as complete and accurate as possible within our time and budget constraints, but we anticipate some errors and omissions. We also recognize that new uranium occurrences not included in this report are being located through industry exploration and as a result of favorability evaluations conducted by subcontractors to Bendix Field Engineering Corporation as part of the NURE program. Data on radioactive occurrences and bibliographic citations have been entered into a mini-computer diskette storage system in such a way that additions and corrections can be made and data retrieved with minimum effort. We therefore welcome comments from users of this report and request that information on new occurrences or corrections be sent to the Colorado Geological Survey, 1313 Sherman Street, Denver, Colorado 80203 so that our records on radioactive occurrences and bibliographic citations may be kept current.

## Acknowledgments

The authors would like to express appreciation to William L. Chenoweth, Eugene W. Grutt, Jr., Ben Bowyer, Carl Roach, Roger Malan, and Holger Albrethsen of the U.S. Department of Energy for their support throughout the project. Special thanks to William Chenoweth, A. S. J. Taylor, and E. P. Beroni for critical review and assistance on the occurrences, bibliography and cross-indexes. We thank also the USGS Library staff, especially I. P. Schultz for assistance in accessing hundreds of open-file reports; T. W. Offield of the USGS Uranium and Thorium Branch for his help and cooperation; and J. William Hasler for assistance in obtaining DMEA information. Thanks are due all of the companies who supported this project. Special thanks to the following companies with offices in Denver, who provided valuable guidelines for the study:

Ashland Oil, Inc.  
Conoco  
Denison Mines Ltd.  
French American Metals Corp.  
Gulf Minerals  
Kerr McGee  
Mobil Oil Corp.  
Power Resources Corp.  
Public Service Co. of Oklahoma  
Rampart Exploration

Rocky Mountain Energy  
Urangesellschaft USA, Inc.  
Uranla  
Union Carbide  
Western Nuclear, Inc.

Additionally, the authors would like to thank their colleagues at the Colorado Geological Survey for their support--especially John Rold for his assistance and support in planning and carrying out the project, Stephen D. Schwachow for critical review and editing of the manuscript, and the excellent secretarial staff of Doris Sweetman, Becky Andrews, Valerie Taylor and Judith Primon, who inputted and edited seemingly endless volumes of data and manuscript. Cheryl Brchan, with assistance from Mark Persichetti and Kim Knowlton, planned and prepared the maps, figures, and layout. Becky Osterwald, Becky Foster, Judith Primon and Molly Orkild did much work in a very short time in order to prepare the camera-ready copy. Special thanks go to Carl Schlaphoff and Toshiko Mihara of Schlaphoff and Associates for patiently working with us in developing customized programs for this project. Their work resulted in assembling this document in a fraction of the time required had the data been compiled manually.

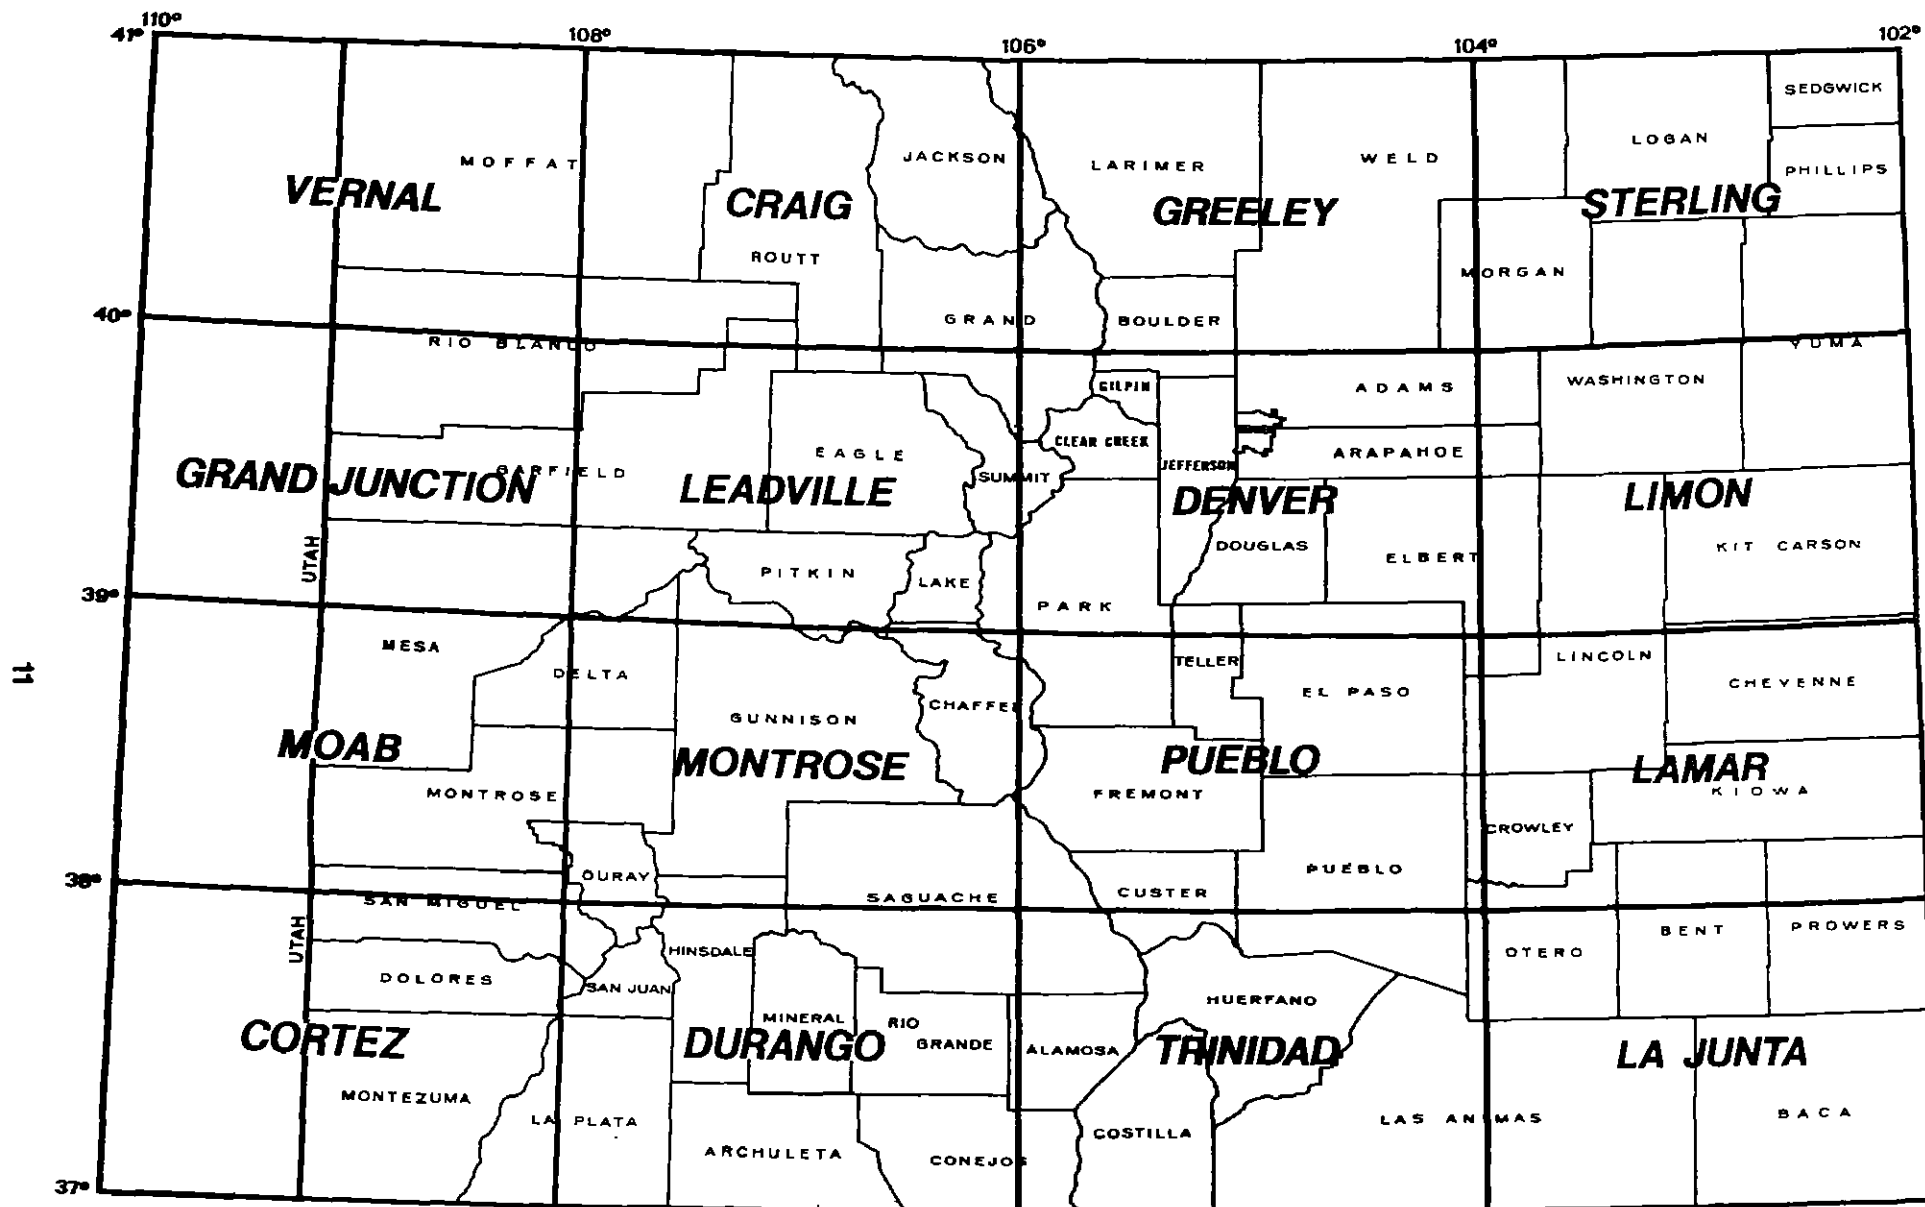

Figure 8. Map of Colorado showing counties and 1° x 2° quadrangles.

**PART ONE**  
**Occurrences**

## Introduction

The following list of occurrences and their descriptions is the most comprehensive set of data on natural radioactive occurrences in Colorado to date. An occurrence for this project was defined as any site with radiation over twice the background rate, or a concentration of uranium or thorium at 0.01% or more. The compilation was carried out from every source of data that could be accessed. The list is as complete as possible to January 1978. The information was arranged to be as useful as possible to all types of readers--geologists, planners, landowners, government agencies, and students.

### DESCRIPTION OF COMPILATION METHODS

There were five major sources for compiling the occurrences:

U.S. Atomic Energy Commission Preliminary Reconnaissance Reports (PRR's).

U.S. Atomic Energy Commission Production Records for Colorado.

U.S. Department of Energy Lease Records for Colorado.

U.S. Geological Survey Computerized Resource Information Bank (CRIB).

Personal and Company Communications.

The Preliminary Reconnaissance Reports (PRR's) are a series of one-page documents describing all sites that were examined for possible radioactive occurrences in the United States. These were visited by U.S. Atomic Energy Commission and U.S. Geological Survey personnel from 1945 to 1960. All of the individual examinations made in a county were released as a single county report. These documents are available from the National Technical Information Service, U.S. Department of Commerce, Springfield, VA 22161. Paper copies of all reports on the counties in Colorado are available for inspection at the Colorado Geological Survey, and the Colorado Division of Mines has microfiche copies of these reports for the entire United States. The reports are now outdated, and the reliability of some are questionable. However, they do describe most of the major occurrences in the state, except those in the Uravan mineral belt on the Colorado Plateau. As such, they are a good base from which to begin compiling occurrences.

The second major source of information was the U.S. Atomic Energy Commission's Production Records, on file at the Grand Junction Office of the Department of Energy. A computer printout of a condensed version is also on file at Colorado Geological Survey. The production records list producing mines in the United States with information on the number of tons and the grade of the ore mined. The information is cumulative from January 1, 1948 to January 1, 1971. Government purchasing of uranium ended on December 31, 1970. Certain properties controlled by the Cotter Corporation and Climax Uranium began

production for sales to private industry as early as 1967. Before 1971 all purchases of uranium ore were made primarily by the U.S. Atomic Energy Commission; hence, any of that tonnage and grade information is now public information. These records were kept on all producing properties; therefore, when a mine dump was later reworked and sent to a mill, it received a new production record. As a result, many mine dumps in the Uravan mineral belt are listed as producers. There was even a production record of the cleanings from barrels that contained yellowcake.

The third source of information was the Department of Energy's Lease Tract Records. The lease tracts are areas of land that have been withdrawn at various times from mineral entry or claiming and later leased by competitive bids for uranium and vanadium production. All of the lease tract areas in Colorado are within the Uravan mineral belt. The records are kept current and contain the number of tons mined, the grade of the ore, and the number of pounds of uranium and vanadium produced. Over a period of years, these tracts have changed boundaries, names, owner, etc. They have been known by various names, including "Reserve Blocks", "Lease Tracts", "Mining Leases", "Lease Units", and "Mineral Leases". Occasionally some of these areas have been restored for standard mineral entry. Following this introduction are tables containing information on the Colorado leased areas, relating former lease units to the current lease unit numbers. The production figures are complete only to 1962. For more up-to-date production numbers, the individual property occurrence listings should be consulted.

The fourth source for compilation was the Computerized Resource Information Bank (CRIB) of the U.S. Geological Survey. This computer data base is currently being operated by the University of Oklahoma at Norman for the Geological Survey. It is a data base containing information on all commodities, their occurrences, reserves, mineralogy and other pertinent data. All of the uranium data had been entered into the data base during 1972 and 1973. It was not possible to check the dates of the information closer than 1973. During 1977 some information from the Defense Minerals Exploration Assistance Program (DMEA) was entered into CRIB. We had early access to the DMEA material and used it as a source for compiling our occurrences. The DMEA program was intended to provide assistance to individuals and companies in the exploration and development of strategic minerals, including uranium. Many properties in Colorado were explored with DMEA funds for uranium and other metals. The reports on the properties are confidential, and only the owner of the property and the U.S. Geological Survey have copies. These reports are both accurate and useful if they are available to an occurrence evaluator.

The fifth source of information was personal interviews and company communications. During the period of this project we contacted every major company and individual that had at some time explored for uranium or investigated uranium or thorium in the state. Many people contacted were very helpful and some even opened their submittal files to us.

A computer printout from the U.S. Bureau of Mines Mines Availability System (MAS), another computer data base, was also used for compiling occurrence records. The information for the MAS file had been researched in 1975. We found that the information differed from the U.S. Geological Survey and the U.S. Atomic Energy Commission's information in many instances. As a result, we used the MAS data only as a secondary source of information. When using any occurrence data where the U.S. Bureau of Mines is the only reference, it should be used with discretion.

Other sources of information for compiling the occurrences included published and unpublished literature on uranium, thorium, and radioactive occurrences in the state. References to most of this literature can be found in the accompanying bibliography.

#### DESCRIPTION OF INFORMATION HEADINGS

When researching the occurrences, we looked for the following 17 types of information. In most cases, all the information was not found and most occurrences will have less than the complete set of data shown below. The four-letter headings used in the occurrence records are mnemonic codes for the information listed below.

NAME---Name. Primary name and any aliases under which the primary occurrence may be found.

LOCATION---Location. Using the land-grid system, the location is given by section, township, and range.

LCST---Location Status. We used either "unsurveyed", "uncertain", or "unlocatable" if we believed there was any question as to the validity of the location. "Unsurveyed" means that the area where the occurrence is located has not been surveyed into the land-grid system; hence, there is a question as to its exact legal description. This is not of great concern to the user since the township and range lines are projected into the area, and most occurrences can be found. "Uncertain" was used when the location, the directions to the occurrence and/or the described geology did not correlate. This status is a more serious problem for the user than "unsurveyed" because the validity of the location is questionable. "Unlocatable" means either no location was given or the location given is obviously incorrect. This category makes the total validity of the occurrence questionable and its value negligible.

QUAD---Topographic Map Quadrangle. The name of the 7 1/2' or 15' U.S. Geological Survey topographic map quadrangle in which the occurrence can be found.

MAP--- 1° x 2° Map Quadrangle. The name of the 1° x 2° map in the pocket of this volume on which the occurrence is plotted.

DEVL---Development. A short description of the type of mining or prospecting that has taken place at the site.

PROD---Tonnage and Grade. The tons and grade of ore mined with the number of pounds of  $U_3O_8$  and  $V_2O_5$  produced.

BKG--- Background Radioactivity---The normal range of the background radiation, reported in either mr/hr (milliroentgens per hour) or cps (counts per second) as measured with a radiation detection device.

RNG--- Range of Radioactivity. Range of the radioactivity that was found at the occurrence, from normal background to a maximum reading. This, like the background, is reported in mr/hr or cps. In a few cases the range is reported as xbg, which means the range of the radioactivity was recorded as a multiplication of the background rate.

HOST---Host Rock. Rock type in which the occurrence is found.

STRT---Structural Controls. Any structure in the rock that may have helped to localize the uranium mineralization.

ALT--- Alteration. Any change in the rock which may be due to emplacement of the uranium or have contributed to the emplacement.

MNZ--- Mineralization. The minerals found at the occurrence and any sample analysis data. The analysis is given as a percentage or as parts per million (ppm) of U (uranium or  $U_3O_8$ ). The symbol for uranium is given as "U", "eU", and "cU". "U" stands for uranium in its elemental form. "eU" is the symbol for "equivalent uranium" which is the amount of uranium as measured on a radiation detection device such as a scintillometer or gelger counter. There is not necessarily any uranium at an occurrence that has "eU". The radiation seen on a counter can be caused by radon, radium, or other daughter products of uranium, or by thorium. "cU" means "chemical uranium", an amount that has been measured chemically and is a true measure of uranium in the sample.

RMKS---Remarks. Any additional pertinent information.

DOI--- Date of Information. Date that is applicable to most of the information given on the occurrence.

REF--- References. These are given in the short citation format of Author and Date. Using this citation, the reference can be found in the accompanying bibliography. For those references that are not listed in the bibliography, a full citation is given. This is not necessarily a complete listing of references for a given property.

#### USE OF OCCURRENCES

The following list of occurrences is arranged alphabetically by county and numbered alphabetically by primary name within each county. The numbers are used to plot the occurrence on the 1° x 2° maps in the pocket at the back of this volume. To facilitate finding occurrences, a complete alphabetized list of occurrence names by county follows the Introduction. The names are given only up to 60 characters in length.

#### MAPS

Sixteen 1° x 2° maps that cover Colorado are shown in the figure on the following page. All natural radioactive occurrences were plotted on these maps, which are included as plates in the pocket at the back of this volume. The La Junta, Lamar, Limon, and Grand Junction sheets were not printed, however,

because there were very few occurrences on these sheets. Maps of those few occurrences were included as figures with the occurrences in the appropriate county occurrence listing. The opposite situation of too many occurrences for the scale of the map appeared with Clear Creek, Gilpin, Mesa, Montrose, and San Miguel Counties. Clear Creek and Gilpin Counties were plotted at 1:125,000 scale and included as figures with their respective county occurrences. Mesa, Montrose, and San Miguel Counties lie within the Ura-van mineral belt and contain about 50 percent of all the occurrences in the state. The area of the Ura-van mineral belt within these three counties was printed as one map at a scale of 1:100,000 and included as a plate in the pocket.

Each occurrence within the county is numbered alphabetically, and plotted on the appropriate 1° x 2° map with a symbol to indicate its host rock, and its number. The host rock symbols were arranged within the following generalized host categories:

- Coal, shale, and limestone
- ▲ Igneous and metamorphic
- Sandstone, arkose, conglomerate, and siltstone, lake sediments
- Spring deposits and ground water
- ◆ Undetermined

This method of plotting the host placed similar rock types together and does not address the question of genesis.

Separate single copies of these maps can be obtained at the office of the Colorado Geological Survey.

## EXPLANATION FOR TABLES 2 & 3

### HISTORY OF LEASING (G. C. Ritter, personal communication)

1945-55	Atomic Energy Commission obtained mineral rights on 700 square miles of land, and conducted exploration.
1953-57	660 square miles were returned to public domain.
1948-56	Deposits leased for mining to operators selected by the Atomic Energy Commission.
1962	By March 31 all leases had expired.
1962-present	Atomic Energy Commission held mineral rights on 40 square miles
1970-71	Environmental studies made and Impact statement prepared on withdrawn lands.
1973	Reestablished leasing program under revised Circular 8--rules and regulations for leasing.
mid 1974	Leases awarded
late 1974	Development began
mid 1975	Ore production began

### Abbreviations and Definitions

ML-15	Mineral Lease (or Mining Lease) 15
C-AM-20	Colorado-Atkinson Mesa, Uravan District-DOE Lease Tract 20
C-BL-23	Colorado-Bitter Creek and Long Park areas, Uravan District - DOE Lease Tract 23
C-CM-24	Colorado-Club Mesa, Uravan District-DOE Lease Tract 24
C-G-26	Colorado-Gateway District-DOE Lease Tract 26
C-JD-9	Colorado-Jo Dandy area, Monogram Mesa-DOE Lease Tract 9
C-LP-23	Colorado-Long Park, Uravan District-DOE Lease Tract 23
C-SM-18	Colorado-Spring Creek Mesa, Uravan District-DOE Lease Tract 18
C-SR-10	Colorado-Slick Rock District-DOE Lease Tract 10
C-WM-17	Colorado-Wedding Bell Mountain, Bull Canyon-DOE Lease Tract 17
U-PM-28	Utah-Polar Mesa-DOE Lease Tract 28
"Withdrawn"	An area of land that the Atomic Energy Commission withdrew from standard mineral entry, later leasing parts of it to private companies for development.
"Restored"	An Atomic Energy Commission withdrawn area that was later restored to standard mineral entry.

"Reserve Blocks" Tracts of land held by the government that contain known reserves. They were identified by the USGB prefix, indicating U.S. Government Block, the reserve block number, a two digit code for the general location, and a final two digit code indicating the government agency responsible for evaluating the property.

The location codes include:

USGB-1-JDGS	Jo Dandy area, Monogram Mesa
USGB-9-JDOR	Jo Dandy area, Monogram Mesa
USGB-1-LGGS	Legin Group, Slick Rock
USGB-2-RGGS	Radium Group, Slick Rock
USGB-3-SPGS	Spud Patch Group, Slick Rock
USGB-5-GTLD	Georgetown Group, Slick Rock
USGB-6-RGOR	Lower Group, Radium Group, Slick Rock
USGB-3-SCGS	Spring Creek Mesa, Uravan
USGB-4-SMGS	Spring Creek Mesa, Uravan
USGB-1-AMGS	Atkinson Mesa, Uravan
USGB-18-AMOR	Atkinson Mesa, Uravan
USGB-9-LPGS	Long Park, Uravan
USGB-13-CMGS	Club Mesa, Uravan

The agency codes are:

GS	Block is the responsibility of the U.S. Geological Survey
LD	Block is the responsibility of the Leasing and Development Branch of the AEC
OR	Block is the responsibility of the Ore Reserves Branch of the AEC

## Occurrences

1. 2000 10 31

## ADAMS COUNTY

There has been no production of uranium from Adams County, nor are any occurrences noted in the county.

The county is mostly covered by Quaternary alluvium, with the Cretaceous Laramie and Fox Hills Formations cropping out in the eastern part of the county.

The potential for uranium resources to be found in the county is small. The Laramie and Fox Hills do contain uranium ore bodies farther north in Weld County, and the possibility exists that these formations might contain sandstone-type uranium occurrences similar to those in Weld County.

## ALAMOSA COUNTY

No occurrences of uranium have been reported in the county.

Almost the entire county is underlain by the late Tertiary Alamosa Formation, which consists of unconsolidated gravels, sands and silts. A small part of eastern Alamosa County consists of Precambrian gneisses and granitic rocks. The county lies astride

the San Luis valley Graben, which is filled with many thousands of feet of gravels and sands similar to the Alamosa Formation.

The potential for occurrences in the county is small. The San Luis Valley sediments show the greatest potential for uranium mineralization, most probably in the form of sandstone-type occurrences.

## ARAPAHOE COUNTY

No uranium occurrences have been reported in Arapahoe County. The geology of the county is relatively simple. Quaternary sands and gravels cover the western part of the county, and the Cretaceous Laramie and

Fox Hills Formations crop out along the eastern edge. These formations contain uranium in Weld County, and the same type of occurrence may be found in Arapahoe County. However, the potential for resources is small.

## ARCHULETA COUNTY

Although no production is reported from Archuleta County, one occurrence has been recorded.

Archuleta County, located in the southwestern part of the state, is dominated by sedimentary rocks ranging from Pennsylvanian in the northwestern corner to Quaternary in the eastern part of the county. Three major structures dominate the county: the northwest-trending San Juan Basin in the southwest, the Archuleta Anticlinorium paralleling the San Juan Basin in the southwest, and the Chama Basin, which in turn parallels the Archuleta Anticlinorium.

No uranium production has taken place in the county, but some exploration and underground work was carried out on the Sunetha Claim Group (Sunetha Anticline). This is the only known uranium prospect in the county and is located on the Sunetha Anticline southwest of Pagosa Springs. The host for the deposit is reported to be the Jurassic Morrison Formation.

Potential for additional uranium resources in the county is small. Areas in the county that may be favorable for such resources include the northwestern section where sandstone-type occurrences may be found in the exposed Jurassic Morrison Formation.

## ARCHULETA COUNTY

### Sunetha Claim Group (Sunetha Anticline)

LOCATION: sec. 34, T. 35 N., R. 2 W.

LCRM The CRIB file lists this location as sec. 21, 28, T. 38 N., R. 2 W.

QUAD Pagosa Junction 15'

MAP DURANGO

DVEL Exploration and some underground work has been carried out.

HOST The deposit occurs in beds of the Jurassic Morrison Formation.

MNZ Uranium and vanadium mineralization were detected, and carnotite was identified.

RMKS The CRIB reference shows this as being in Archuleta County; however, the location falls in Mineral County. Also there are Tertiary volcanics at the CRIB location and no Morrison Formation.

DOI 1975

REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. Geol. Survey, 1977, CRIB file.

## BACA COUNTY

No production of uranium and no uranium occurrences have been reported from Baca County.

The rocks exposed in Baca County are primarily of sedimentary origin, ranging in age from Permian to Quaternary. Although the surface geology of the county is largely dominated by unconsolidated Quaternary and Tertiary sediments, some Tertiary dikes and lava flows occur in the southwest. Most of the formations are flat-lying, but small monoclines and anticlines do occur.

Uranium resource potential is limited in the county. Water sampling in the central Great Plains, however, has shown some increase of uranium from the

waters in certain parts of the county. Analyses in the county from wells, streams, and springs range from less than 1 ppb to 35 ppb, with most samples ranging between 2 and 20 ppb. Values of the water samples increase near the northwest part of the county on the flank of the Las Animas Arch near Two Butte Creek and Hackberry Creek.

The most favorable formation for uranium resources in the county is the Triassic Dockum Group, which is exposed along Two Butte Creek and in the southwestern part of the county. In the past, minor gold, silver, and copper were mined from the Jurassic Entrada Sandstone, and it may also warrant further investigation for uranium occurrences.

## BENT COUNTY

No uranium production has been recorded from this county. Bent County is located in the southeastern part of the state and is underlain by sedimentary rocks ranging in age from Jurassic to Tertiary. The majority of these rocks are the Lower Cretaceous Dakota Sandstone and the Upper Cretaceous Colorado Group. Surfactially, the county is dominated by the flood-plain deposits of the Arkansas River.

Although no uranium production has come from the county, several uranium occurrences are known. Probably the most important of these is the Allen Jones Property, which is an old copper prospect in the Jurassic Morrison Formation.

Uranium occurrences are known in the area south of the Arkansas River and in the southwestern part

of the county. These are found in facies of the Dakota Sandstone and the Morrison Formation. These formations are also favorable for further discoveries of uranium. Due to the low topography in the county, much exploration is done by sampling wells, springs, and streams. Water sampling done by the U.S. Geological Survey showed higher than average uranium values in the Rule Creek drainage basin, especially in those areas draining the Cheyenne Sandstone Member of the Purgatoire Formation. The highest values come from samples taken on the north flank of the Las Animas Arch. Water from the Ogallala Formation north of the Arkansas River also shows high uranium values, and may warrant further study.

## BOULDER COUNTY

As of 1971, 22,127 tons containing 188,648 lb of  $U_3O_8$  had been mined in Boulder County, making it one of the major uranium-producing counties in the state. The potential for more reserves to be found in the county is quite favorable.

The county is divided into two different geologic terranes. The eastern part of the county is underlain by sedimentary rocks, ranging from Pennsylvanian to Quaternary in age. The strata are flat-lying except near the mountain front where they are upturned to the east. West of the mountain front the Precambrian metamorphic rocks are most abundant rock type. They are cut by numerous northwest-southeast trending faults or breccia systems. They are also the hosts for the uranium producers. The most important producers in the county were the Fairday Mine and the Victory Mine.

Both of these mines lie in the Jamestown mining district, which produced gold, silver, and fluorite.

The Fairday produced 20,934 tons containing 182,679 lb of  $U_3O_8$ , and the Victory produced 595 tons containing 1,908 lb of  $U_3O_8$ . Both mines produced uraninite from Tertiary veins within Precambrian metamorphics and Tertiary Intrusives. The uraninite was associated with the primary precious-metal minerals and found in a number of mines. The one exception was the Fairday Mine where only pyrite and quartz were associated with the uraninite.

There is moderate potential for reserves to be found in the county. Vein-type deposits in the crystalline rocks of the Front Range have the most potential for future reserves in the county. The soda granite on Porphyry Mountain north of Jamestown is an example of alkaline rocks that are being studied as possible hosts for uranium. For further information see Murphy, M., and others, 1978, U.S. Department of Energy GJBX-(78)78, 183 p.

## CHAFFEE COUNTY

AEC records show no production of uranium from Chaffee County. Potential for reserves to be found within the county is small.

Chaffee County is situated in the central part of the state. The Arkansas River flows south through the east-central part of the county. Sedimentary rocks of Cambrian to Permian age and Precambrian granites cover the quarter of the county east of the alluvial valley of the Arkansas River. Precambrian gneisses and schists dominate the northwestern, southwestern, and southeastern areas. Later Tertiary (primarily Miocene) extrusives are often found associated with these early Tertiary intrusives. Several base- and precious-metal mining districts are located in the mountainous areas.

Uranium is found in a number of mines in the metal mining districts of the county, but all of the mine production was base- and precious-metals or other products, with none for uranium.

The largest concentrations of radioactive occurrences are located in mines and prospects east of the Arkansas River. Most of the occurrences are clustered in T 14 S, R 77 W (near the Free Gold and Trout Creek districts) and in the Calumet district.

There is some potential for reserves of uranium to be found in the county. The area with the greatest potential for new uranium reserves is the Monarch mining district. Although that part of the district within Chaffee County has had no uranium production, the portions within Gunnison and Saguache Counties have reported some, with new production about to begin. Such basic structures as the Chester Fault, which extends into Chaffee County, may contain mineralization. Any additional areas within the county where Precambrian complexes are intruded by the varied Tertiary intrusives provide favorable areas for prospecting for vein-type uranium deposits.

### Gold Bug Claim

LOCATION: sec. 21, T. 51 N., R. 9 E.  
 LCRM The claim is 1/2 mile northeast of Turret on the south side of the truck trail.  
 QUAD Cameron Mountain 15'  
 MAP PUEBLO  
 DVEL The Gold Bug shaft was reportedly sunk to a depth of 500 ft. It was originally developed as a gold mine. The underground workings

are now caved and abandoned.

BKG 60 cps  
 RNG 300 to 950 cps  
 HOST The shaft is sunk in Precambrian granite.  
 MNZ Mineralization is in narrow veins of quartz with scant gold-bearing pyrite and ilmonite. The veins strike N80°W and dip 76°N. A grab sample from the dump shows 0.46% eU, 0.28% U and 0.05% V205. Several other samples assay between 0.002 and 0.012% U308. However, the radioactivity was found in only a small area of the dump. The anomaly could not be located in 1977.  
 DOI 1952  
 REF U.S. Geol. Survey, 1977, CRIB File. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Chaffee County, Colorado.

### Josephine Mine

LOCATION: SW1/4 sec. 35, T. 12 S., R. 79 W.  
 LCST UNCERTAIN  
 LCRM "The mine is ten miles north of Buena Vista on U.S. 285, then cross the Arkansas River on the dirt road at the fire station. The mine is 59 yds east of the river."  
 QUAD Buena Vista 15'  
 MAP MONTROSE  
 DVEL There is one tunnel that is 305 ft long.  
 RNG To 3 x bg  
 HOST The host consists of Tertiary rhyolite and diabase dikes in gneiss of the Precambrian Pikes Peak Granite. The radioactivity is confined to serpentinized diabase in a 2-ft wide shear zone at the contact between the diabase and the granite.  
 STRC Minor shears also show some radioactivity in the area of the major shear zone.  
 MNZ The radioactive minerals are unknown, but could be associated with ilmonite staining in the shear zone.  
 DOI 1953  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Chaffee County, Colorado.

### Little Jimie 5

LOCATION: NW1/4NE1/4 sec. 6, T. 49 N., R. 7 E.  
 QUAD Poncha Springs 15'  
 MAP MONTROSE  
 DVEL There is an adit bearing southeast into the hill. It is inaccessible, but was reported to be 600 ft long.  
 BKG .1 mr/hr  
 RNG To .7 mr/hr  
 HOST The mineralization occurs in veins (Tertiary?) cutting Precambrian granite and schist.  
 STRC The vein appears to strike E to NE, and dips steeply.  
 MNZ Primary ore minerals include chalcopyrite, galena, and thorite (?). Secondary minerals present are malachite and azurite, with quartz and ilmonite forming the gangue. The ores and gangue are intergrown and crudely banded.  
 DOI 1952  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Chaffee County, Colorado.

## CHAFFEE COUNTY

### Lucky Break Placer (Lucky Break Iron Mine)

LOCATION: SW1/4NW1/4 sec. 2, T. 50 N., R. 9 E.  
 QUAD Cameron Mountain 15'  
 MAP PUEBLO  
 DVEL There is an open pit, roughly 150 ft in diameter and 100 ft deep, with a 75 ft adit.  
 HOST The host is an undifferentiated limestone composed of Upper Devonian Dyer Dolomite (Chaffee Group) and Mississippian Leadville Limestone.  
 STRC The deposit lies on a N to NW trending normal fault which dips steeply to the east.  
 ALT Intense alteration has taken place and obscured the fault in the vicinity of the mine.  
 MNZ Mineralization consists of massive red and black bands of iron oxides (hematite, goethite) replacing the limestone. Grab samples of these iron oxides assayed between 0.002 and 0.069% eU308, while assay data submitted by the owner to the U.S. A.E.C. showed 0.23 to 0.30% U308. The more radioactive samples show small fractures filled with late quartz. The radioactive specimens are also enriched in Cu, Zn, Co, Be, Y, while being depleted in Al, Ti, Ca, Mg, Na, K, Ba, Sr, Ga, Zr, as compared to the nonradioactive specimens.  
 DOI 1959  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Chaffee County, Colorado. Lovering, T. G., and Beroni, E. P., 1959, p. 356-358.

### Lucky John 2

LOCATION: sec. 22, T. 51 N., R. 9 E.  
 QUAD Cameron Mountain 15'  
 MAP PUEBLO  
 DVEL The owners sank a small shaft on a 4 ft dike.  
 BKG .08 mr/hr  
 RNG to .12 mr/hr  
 HOST The host rock is Precambrian granite cut by a ferromagnesian dike.  
 STRC The dike strikes N76°E and dips 80°NW.  
 MNZ The radioactivity is moderate, and is associated with magnetite. Samples collected assayed 0.061 to 0.098% U308, 0.54 to 0.74% ThO2, and 1.02 to 1.58% rare earths.  
 DOI 1952-1954

### Mica Beryl Claims (Falfar, Gray Hen)

LOCATION: sec. 27, T. 51 N., R. 9 E.  
 QUAD Cameron Mountain 15'  
 MAP PUEBLO  
 DVEL The claim was located in 1942, and produced some feldspar and mica.  
 PROD Twenty-one tons of beryl were mined that brought \$203/ton. During 1949-50, the mine produced 5,000 tons of feldspar and 300 tons of scrap mica.  
 HOST The host rock is a pink, medium- to coarse-grained Precambrian granite with visible flow structures and a prominent joint set. Pegmatite dikes cut the granite.  
 STRC The joint set possibly controlled the emplacement of the pegmatite dikes. They strike N80°E and dip 70°N.  
 MNZ Mineralization lies in the zoned pegmatite which consists of extremely coarse-grained quartz (crystals up to 2 ft in diameter) intergrown with a good grade of feldspar and mica. Some beryl is present in crystals up to 6 in. in diameter. Close examination of several areas of abnormal radioactivity revealed small amounts of monazite and samarskite. Assay of three selected samples had values up to 1.29% U308.  
 DOI 1950  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Chaffee County, Colorado.

## CHEYENNE COUNTY

There has been no uranium production from Cheyenne County. Cheyenne County is located on the eastern plains of Colorado. The county is both topographically and geologically flat-lying, with Upper Cretaceous Pierre Shale surfacing in the western half and Miocene-Pliocene Ogallala Formation in the eastern half. Upper Cretaceous rocks crop out along the stream beds of Rush Creek and Big Sandy River.

The one small uranium occurrence that has been recorded in the county is located in the Sharon Springs Member of the Pierre Shale.

Due to lack of outcrops within the county, much of the exploration to date has been in the form of water sampling of wells, springs, and streams. Higher than average uranium values have come from samples taken from drainages on the northern flank of the Las Animas Arch. Water from the Ogallala Formation shows higher than average uranium values. Both the Sharon Springs Member of the Pierre Shale and the Ogallala Formation are favorable units for further exploration for uranium resources.

## CLEAR CREEK COUNTY

Clear Creek County, located within the Front Range mineral belt, is the site of several famous metal-mining districts that were active during the late 1800's and early 1900's. Precambrian rocks of the Idaho Springs Formation, the Boulder Creek Granite, and the Silver Plume Granite cover much of the county. Sills, dikes, and stocks of early Tertiary age intrude the Precambrian rocks, and many of the county's ore deposits are associated with these intrusive porphyries. Uranium occurs as a localized, minor component of many of these ore deposits.

Of 66 known uranium occurrences within the county, only five have recorded production, and that totalled only 162 tons of ore at an average grade of 0.16 percent  $U_3O_8$ , producing 518 pounds of  $U_3O_8$ .

The Highlander Mine and the Spanish Bar Mine produced the largest amounts of uranium ore in the county. The Jo Reynolds and Almaden Mines are reported

in some literature as containing the most anomalous radioactivity. These mines are typical of occurrences within the county. They are found in Precambrian metamorphics that have been cut by Tertiary intrusive porphyries and Laramide age veins. These mineralized veins were actively mined in the past for base and precious metals. The uranium present in these veins often occurs as uraninite, associated with chalcopyrite, galena, and sphalerite. Uranium mineralization appears to have occurred both before and after base- and precious-metal sulfide mineralization. Secondary minerals and radioactive hydrocarbons have been reported from a number of mines.

It is unlikely that Clear Creek County will ever be a large uranium producer because the vein occurrences are too small and scattered. If any of the old mines are reopened, or if new mines are developed for base- and precious-metals, then it is possible that uranium could be recovered as a by-product.

LOCATION: sec. 3, T. 4 S., R. 73 W.  
 LCST UNCERTAIN  
 LCRM Original directions to mine are as follows: "Along Spring Creek gulch for 0.9 miles. Mine portal is on south side of road across Spring Creek gulch and is 80 ft south of Coffindaffer home".  
 QUAD Idaho Springs 7 1/2'  
 MAP DENVER  
 DVEL An 800 ft tunnel was driven.  
 RNG To 4 x bg  
 HOST A Tertiary bostonite dike contains the mineralization.  
 DOI 1951  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Clear Creek County, Colorado.

## Major C. and Little Colonial

LOCATION: sec. 20, T. 3 S., R. 73 W.  
 LCST UNSURVEYED  
 LCRM East from Dumont 0.9 miles to the second gulch; proceed north up the gulch to the first dump on the east.  
 QUAD Central City 7 1/2'  
 MAP DENVER  
 DVEL There is a tunnel on the property.  
 BKG 75 to 80 cps  
 RNG 170 to 175 cps  
 HOST The host is Precambrian Idaho Springs Formation, which is cut by Tertiary veins.  
 MNZ Ore minerals are chalcopryrite and ilmonite in a gangue of quartz and pyrite. A grab sample of the ilmonitic material assayed 0.001% cU and 0.014% eU.  
 DOI 1952  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Clear Creek County, Colorado.

## Martha E Mine (Elizabeth M Lode)

LOCATION: SE1/4NE1/4 sec. 5, T. 4 S., R. 73 W.  
 QUAD Idaho Springs 7 1/2'  
 MAP DENVER  
 DVEL The tunnel extended at least 152 ft from the portal.  
 PROD In 1954, 1 ton of ore averaging 0.14% U3O8 and containing 3 lbs U3O8 was produced.  
 RNG 2 to 4 x bg  
 HOST The deposit occurs in Tertiary veins within the Precambrian Idaho Springs Formation, which consists primarily of schist with thin seams of pegmatite.  
 STRC The ore was deposited in veins following the schist foliation.  
 MNZ Mineralization consists of low grade gold ore (reported \$4/ton), which is iron stained and vuggy. No sulfides were visible. A green, radioactive mineral (torbernite?) is present in small fractures in the schist. Channel samples from inside the mine all show weak radioactivity.  
 DOI 1950  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Clear Creek County, Colorado. U.S. A.E.C., 1971, Production Records, Colorado. Bastin and Hill, 1917, U.S. Geol. Survey Prof. Paper 94.

## Miller Tunnel

LOCATION: SW1/4SE1/4NE1/4 sec. 6, T. 4 S., R. 73 W.  
 QUAD Idaho Springs 7 1/2'  
 MAP DENVER  
 DVEL There is at least 900 ft of cross-cut tunnel and drifts.  
 PROD Between 1908 and 1940, a total of 160 tons of ore was produced, yielding gold, silver, copper, lead, and zinc. No uranium ore was shipped.  
 BKG .01 mr/hr  
 RNG .03 to .04 mr/hr  
 HOST The host rock is Precambrian in age, and the mine lies near the boundary between the Idaho Springs Formation and the biotite-muscovite Silver Plume granite. Granite gneiss and bostonite also are present.  
 STRC The Miller vein strikes N63°E and dips on the average of about 8°NW.  
 MNZ Minerals observed include galena, sphalerite, chalcopryrite, and pyrite, with secondary ilmonite and torbernite in scattered disseminated flakes. The gangue is quartz and brecciated bedrock. Grab samples analyzed contain between 0.006 and 0.014% eU and between 0.001 and 0.004% cU.  
 DOI 1952  
 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Clear Creek County, Colorado. Harrison and Wells, 1956, p. 79, 82, 113-114. Spurr, Garrey, and Ball, 1908, U.S. Geol. Survey Prof. Paper 63, p. 334-335.

## Muscovite Mine

## CONEJOS COUNTY

Very limited uranium production has come from this county. In fact the producing deposit is also the only recorded occurrence of uranium.

The county is divided geologically into two terranes. The eastern half is underlain by Tertiary sediments filling the huge San Luis Valley Graben. The western half of the county is mountainous and covered by Tertiary volcanics associated with the two calderas in the northern part of the county--the Summitville and the Platoro Calderas.

The only producing occurrence in the county is the Shirley Rae Deposit, but its location is unknown. By 1971, 4 tons of ore containing one lb of  $U_3O_8$

had been mined from this deposit. The geology of the county is not favorable for the occurrence of uranium, and this fact combined with an unknown location casts doubt on the validity of the occurrence. It is possible that sandstone-type deposits occur in the sediments filling the San Luis Valley, but of more importance is a new type of uranium occurrence that is associated with volcanogenic rocks. The two calderas in northwest Conejos County thus appear to have limited favorability for uranium resources. Also, as more research is carried out, volcanogenic-type occurrences may become economically important in the future. However, from the present state of knowledge this county has very small potential for developable reserves.

## COSTILLA COUNTY

Minor production from Costilla County consisted of 0.75 tons of ore that yielded 3.3 pounds of  $U_3O_8$ .

The geology of the county is complex. The two main structural elements in the county are the Sangre de Cristo Mountains and the San Luis Graben Valley. Precambrian alaskite granites, gneissic granodiorite and other minor gneisses are exposed in the Sangre de Cristo Mountains and Culebra Range in the northern and eastern parts of the county. The Quaternary Alamosa Formation crops out in the San Luis Valley and consists of unconsolidated sands and gravel. Tertiary lava flows and tuffs are widespread in the southeastern half of the county.

The producing deposit in the county was the Black Jack No. 2 Deposit. It produced from sandstone in the Permian Sangre de Cristo Formation. The ore at the mine is reported to be carnotite.

There is potential for reserves to be found in the county. All the occurrences within the county lie in the Permo-Pennsylvanian Sangre de Cristo Formation in the northeastern part of the county. These occurrences are a continuation of a mineralized belt within the Sangre de Cristo Formation.

This belt is continuous along the Sangre de Cristo Range from New Mexico into Custer County. The occurrences are characterized by uranium, vanadium, and copper minerals in silty sandstone and sandy siltstone containing abundant organic material. This type of occurrence has potential but its development is seriously limited by steep dips, high elevations, and rugged topography.

## CROWLEY COUNTY

No production has been reported for the county, and potential for uranium resources to be developed in the county is very minor.

Crowley County is entirely surfaced by sedimentary rocks predominantly of the Miocene-Pliocene Ogallala Formation and the Upper Cretaceous Pierre Shale. The southwestern end of the Las Animas Arch extends into the county.

One small uranium occurrence is known within Crowley County. This occurrence is located in the

Sharon Springs Member of the Pierre Shale and is associated with iron carbonate.

The Ogallala Formation has shown higher than average uranium values from water samples taken in the county and in areas adjacent to the county. It could possibly warrant further exploration for uranium. The Sharon Springs Member of the Pierre Shale is known to contain uranium mineralization both in Colorado and adjacent states, and may also be a favorable unit for uranium resources.

## CUSTER COUNTY

Custer County contains both uranium and thorium occurrences. The Wet Mountain thorium district is one of two in the state, and one of the few in the United States. The potential for reserves to be found in the county are problematic. Thorium is not now a widely sought commodity, and the uranium occurrences are found in an area under study for wilderness designation. Production to date is 8 tons at 0.11 percent  $U_3O_8$ .

Custer County is situated in the south-central part of the state. It is bounded by the Sangre de Cristo Mountains on the west and by the Wet Mountains on the east with the Wet Mountain Valley between the two ranges. The core of the Wet Mountains is composed of Precambrian igneous and metamorphic rocks, overlain on the west by Miocene volcanics and intrusives and on the east by Pennsylvanian to Cretaceous sedimentary rocks. The Wet Mountain Valley is a graben filled with thick Tertiary and Quaternary sediments. Pennsylvanian and Permian sediments crop out over most of the Sangre de Cristo Range. Recent alluvial fans and torrential wash form a broad apron at the base of the Sangre de Cristo Mountains.

There has not been much uranium or thorium production from the county. A total of about 9 tons of ore was shipped, primarily as test shipments. Most of that ore (8 tons) came from the Floyd Watters Ranch and had an average grade of 0.11 percent  $U_3O_8$ . This property produced from a limonite carbonate vein in Precambrian gneiss. Thorium was more abundant than uranium, as were rare earth minerals. This prospect is a typical example of radioactive occurrences in the Wet Mountain district.

Important occurrences within the county fall into two categories: thorium deposits in the Wet Mountains and uranium deposits in the Pennsylvanian-Permian sedimentary beds. The most extensively prospected thorium deposits lie in an area about 12 miles long and 6 miles wide, extending from the Haputa Ranch north-northwest into Fremont County. The larger overall thorium-bearing district, discovered by the U.S. Geological Survey, is about 20 miles long and 10 miles wide. The Tertiary-age thorium deposits occur in northwest-

treaching shear zones associated with barite-sulfide veins that cut such Precambrian complexes as amphibolite, biotite-granite gneiss, metagabbro, migmatite, microcline granite, pegmatites, white granite, and syenite. Premineralization basic dikes occur along the shear zones. The minerals found in the shear zones include thorite, barite, quartz, galena, fluorite, limonite, pyrite, and rare-earth oxides and uranium minerals, but the uranium is minor compared to the thorium. The largest thorium-bearing ore body known is 300 ft long, 26 ft wide, and 400 ft deep, with channel samples that had maximum values of 4.5 percent  $eThO_2$  and 0.002 percent U (Del Rio, 1960, p. 110). The thorite and rare-earths occur as fracture fillings and coatings, and as replacement bodies in sheared rocks. A close association exists with sulfides, barite, and fluorite mineralization, all tentatively classed as Tertiary in age.

In searching for additional thorium deposits of this type, any shear zones in the county should be investigated. The most favorable areas can be recognized by 1) radioactivity, 2) siderite, quartz, and/or barite, 3) basic rocks, often altered completely to limonite, 4) fetid odor of altered rocks, 5) rad-stained rocks, and 6) green or blue amphibolite minerals coating fractures.

Uranium occurrences are primarily located in the Crestone Needles area, around Horn Peak, and all along the Sangre de Cristo Range in bedded deposits of Pennsylvanian and Permian age. Most occur in slightly metamorphosed conglomerates, arkosic sandstones, siltstones, and shales in the Maroon Formation. Where the beds are most radioactive they become very dense and black and contain abundant asphaltic material.

In Custer County, mildly metamorphosed mudstones and asphalt-bearing sandstones of Pennsylvanian and Permian age in the Sangre de Cristos are the host rocks with the most potential. The uranium deposits would probably be of a low-grade, bedded type, either oxidized or unoxidized.

## DELTA COUNTY

There has been no production of uranium from Delta County, and the potential for reserves within the county is small.

The county is largely underlain by Cretaceous and Tertiary sediments. A large portion is covered by three formations, the Upper Cretaceous Mancos Shale and Mesaverde Group, and the Tertiary Wasatch Formation. On the northern edge of the county volcanic rocks cover Grand Mesa.

Six of the eight occurrences in the county are radioactive springs. The other two occurrences are of the sandstone type, but the validity of one is

questionable. One reason for the low uranium potential is that most spring occurrences do not indicate ore bodies. Secondly, the Upper Cretaceous and Tertiary rock units in the county are not considered favorable hosts for uranium. Although host rocks that characterize the Uravan mineral belt are found in the subsurface of Delta County, the projected trends from that belt do not point to Delta County. One final point, however, is that some springs in the county are radioactive due to uranium. Most radioactive springs are anomalous due to radium and radon. This difference may indicate possible uranium mineralization at depth in the area of the springs.

## DENVER COUNTY

Although no occurrences of uranium have been reported in the county, a slight possibility exists that occurrences may be found in the subsurface. However, the probability that they would ever be exploited is extremely small.

## DOLORES COUNTY

Production from the county has not been great. About 285 tons of uranium/vanadium ore were mined in the county as of 1971. Nearly half of that came from the South Barlow Mine, which produced ore from the Jurassic Entrada Sandstone. Several of the smaller mines were listed with production from the Jurassic Morrison Formation. Potential for reserves to be found in the county is favorable even though the county lies south of the Uravan belt.

Dolores County is in the southwestern part of the state in typical sedimentary terrane of the Colorado Plateau. The western part of the county is dominated by plateaus and mesas capped by Cretaceous Dakota Sandstone, with Pennsylvanian to Jurassic sediments exposed in the canyons between the mesas. The central part of the county is largely covered by the Upper Cretaceous Mancos Shale and the Mesaverde Group, with older formations exposed along the flanks of the drainages. The Rico Uplift and its associated features dominate the structural picture in the eastern part of the

county. The uplift was caused by laccolithic and sheet intrusion of magmas into the sediments and by vertical uplift. The Dolores River and its tributaries deeply dissect the uplifted rocks.

The two most important occurrences in the county are the Blue Eagle Mine and the South Barlow Mine. The Blue Eagle Mine produced ore from the Salt Wash Member of the Jurassic Morrison Formation. The South Barlow Mine produced from the Jurassic Entrada Sandstone. These mines, as well as the others, lie primarily in two areas, near Duntan, and along the Dolores River.

The county lies southeast of the primary uranium-producing areas of the Colorado Plateau, but carnotite deposits are found in many exposures of the Jurassic Morrison and Entrada Formations. Areas with potential for further reserves include exposures of these two formations, especially along the course of the Dolores River and along the county's northwestern borders where mining is still taking place.

## DOUGLAS COUNTY

There has been no production of uranium from Douglas County. Few occurrences have been reported within the county.

The county is divided into two geological terranes. The eastern part of the county is underlain by flat-lying Tertiary sediments. The western half is a complex area of Precambrian rocks, including the Pikes Peak Granite and gneisses, schists and quartzite of the Idaho Springs Formation. The northern end of the Woodland Park Graben extends into the southern part of the county.

Two occurrences are associated with shear zones and pegmatites in the Precambrian rocks. A third

occurrence is found in clay in the sediments of the Dawson Formation from the northeastern section of the county.

There is some potential for resources to be found in both geological environments. The eastern part of the county is in the Denver Basin. There has been considerable interest in the basin as a host for sandstone type occurrences, especially in the Tertiary Dawson Arkose. However, no commercial deposits are known within the formation. The Precambrian rocks of the Idaho Springs Formation are the hosts for uranium at the important Schwartzwalder Mine near Golden, and the potential exists for a similar type of deposit in Douglas County.

## EAGLE COUNTY

Production from Eagle County has been negligible. Records show that by 1971 5 tons of ore had been mined, producing 29 lb of  $U_3O_8$ . There is potential for more ore to be produced from Eagle County.

The geology of the county is complex. Rocks and structures of all types and ages are found within its boundaries. The four major structures in the county are the White River Uplift, the Sawatch Uplift, the Eagle Basin, and the Homestake Shear Zone. The Homestake Shear Zone is a major zone of dislocation in Precambrian rocks of the Sawatch Uplift. In southeastern Eagle County the uplift exposes Precambrian granite gneisses and migmatites. The Eagle Basin is a late Paleozoic depositional trough that contains large volumes of gypsum, anhydrite, and salt. Uranium occurrences are recorded in many of these rock types in or adjacent to Eagle County.

Of the 13 occurrences noted in the county, the only two that have recorded production are the Arrowhead 1 and Dorado Claims.

The Arrowhead 1 Claim, located on Red and White Mountain in the center of the county, produced ore from the

Triassic Chinle Formation. Another nonproducing occurrence lies in the same area.

The Dorado Claims, located 6 miles west of Vail Pass, produced from the Permo-Pennsylvanian Maroon Formation. Drilling was carried out on the property during the 1950's; however, the area where the drilling delineated some reserves is now covered by Interstate Highway 70.

Eagle County has some potential for uranium reserves. As noted before, many of the rock types contain occurrences within the county or adjoining counties. The Morrison Formation and the Chinle Formation show potential for sandstone-type deposits. Many occurrences in the northern part of the county that have no recorded production are all associated with the Cambrian Sawatch Quartzite and appear to be unconformity-related types of occurrences. A number of occurrences are found in the Tertiary Troublesome Formation and the North Park Formation in the counties to the north. This suggests some potential for similar deposits in the northeastern part of Eagle County.

## ELBERT COUNTY

No production has been recorded from Elbert County, which lies in north-central Colorado on the Great Plains. Only one occurrence is reported.

The county is within the structural Denver Basin. The Tertiary Dawson Arkose, Denver Formation, and the Cretaceous Laramie Formations and Fox Hills Sandstone that crop out within the county dip gently toward the center of the basin. Exploration has been sporadic in the county. Although the Dawson Arkose has been a favorable exploration target, apparently no significant anomalies have been found.

The one radioactive occurrence in the county is of thorium and not uranium and consists of an ancient placer deposit of heavy-mineral black sand. The probability that this deposit will become economic is small. Potential uranium reserves could be found in sandstone-type deposits in the Tertiary Dawson Arkose and Cretaceous Laramie-Foxhills Formations host rocks. Much water sampling has identified anomalies in Douglas County and in El Paso.

Base from U.S.G.S.

PROD No production.

HOST Brown to black friable sandstone of the lower part of the Upper Cretaceous Laramie Formation. This bed was deposited as a heavy minerals breach placer in a regressive sandstone series similar to placer deposits of the same age in New Mexico and southwest Colorado.

MNZ Minerals include garnet, zircon, and magnetite. These minerals are concentrated in thin bands separated by sandstone with lesser amounts of minerals. Drill cuttings had the following values: %U308 .014-.020; %U308 .005; %ThO2 .05-.07.

DOI 1959

REF R. C. Malan, 1978, Personal Communication.

## EL PASO COUNTY

Production from the county has been small with only 108 tons of recorded production containing 277 lb of  $U_3O_8$ . There is potential for more reserves to be found in the county.

El Paso County lies in the east-central part of the state. The geology is divided into Precambrian rocks in the Front Range and Rampart Range on the west and sedimentary rocks in the Denver Basin on the east. Through the center of the county lie steeply upturned beds along the western edge of the Denver Basin abutting the eastern margin of the mountains. A complete range of Paleozoic through Cenozoic rocks are exposed in the county.

Five hundred tons of ore yielding both uranium and thorium are reported to have come from the St. Peters Dome 1, a mine in the Precambrian Mt. Rosa Granite. However, no production for this mine was recorded in the AEC Production Records. The second (?) largest producer in the county was the Lucky Ben lease. The deposit, found in the Cretaceous Dakota Sandstone, yielded 108 tons of uranium ore containing 277 lb of  $U_3O_8$ .

Important radioactive occurrences within the county fall into two broad categories: uranium, thorium, and rare earths in the Precambrian rocks, and uranium in the sedimentary rocks along the front of the Rampart Range. The Precambrian rocks around St. Peters Dome and Mount Rosa area contain uranium, thorium, and rare earths in veins, stringers, and pegmatites, with some possible segregation of the various elements. Uranium occurrences have been reported in the Pennsylvanian Fountain Formation, Jurassic Morrison Formation, Lower Cretaceous Dakota Sandstone, Upper Cretaceous Fox Hills Sandstone, and the Tertiary Dawson Formation

and Ogallala Formation. The Dakota Sandstone on the east flank of the Turkey Creek anticline, southwestern El Paso County, contains coffinite and uraninite ore. The ore, approximately 80 ft deep, is concentrated in irregular but concordant bodies up to a few hundred tons in size. These are deposits similar to those found in the George Avery Mine in El Paso County, and are examples of the types of ore bodies being sought in the Dakota Sandstone.

Much exploration has taken place and is continuing in El Paso County. Uranium and radioactive occurrences have been found in many of the formations, but those with the most potential are the upturned continental sedimentary rocks along the front of the Rampart Range. These rocks have the best potential because the largest known and highest grade ore bodies found so far in the United States (95%) have occurred in sedimentary formations. Of these, particular attention should be paid to the Dakota Sandstone in the southwestern part of the county, where occurrences are found.

Another rock type with some potential is the Mount Rosa Granite. As mentioned before, it contains uranium and thorium in shears and veins. The granite is an alkaline granite, a rock type just now receiving attention as a new type of uranium host. A report on the subject of alkaline rocks was published as this report went to press. Those who are interested should consult Murphy, M., and others, 1978, Uranium in Alkaline Rocks, U.S. Department of Energy, Grand Junction Office, GJBX-(78)78, 185 p.

## FREMONT COUNTY

Production of either uranium or thorium in the county has been largely limited to uranium from the Tallahassee Creek district. Of 93,949 tons of uranium ore mined and shipped from the county as of 1971, approximately 85,000 tons came from the Tallahassee Creek district. The average grade for the county was 0.25 percent  $U_3O_8$  and total production yielded 464,203 lb of concentrate.

Fremont County encompasses a broad variety of geologic terranes. In the eastern part of the county an extension of the Colorado plains section forms the Canon City Embayment. Here sedimentary rocks ranging from Cambrian to Upper Cretaceous are exposed. West and north of the embayment, Precambrian crystalline rocks of the Front Range and the Wet Mountains cross the county. The northwestern edge of the county borders the Tertiary sedimentary and volcanic sequences in southern South Park. Small, upland, Tertiary Intermontane basins found along the edges of the mountains are associated with the extensive Tertiary Intrusives and extrusives of the Thirtynine Mile volcanic field. Because of the geologic variety within the county, mineral resources are also varied, ranging from sand and gravel deposits to gemstones, petroleum, base and precious metals, coal, thorium, and uranium.

Besides the Tallahassee Creek area, small amounts of ore were mined from the High Park area, from the Dakota Sandstone in the Canon City Embayment, and from the shear zones in the Precambrian Granites near Cotopaxi.

The Tallahassee Creek mining district is located on the southeastern edge of the Thirtynine Mile volcanic field. The uranium deposits lie in fluvial arkosic and volcanic detritus of late Eocene age occupying paleodrainages in the pre-volcanic erosional surface. The deposits are generally stratiform and less than 200 ft deep. The primary ore is dominantly uraninite in unoxidized sediments, but some secondary, oxidized uranium minerals are also found. These basins and the sediments are nearly identical to those in Wyoming, where extremely large uranium deposits are mined.

The first deposits of this type in Fremont County were discovered in 1954 because of two strong radiometric anomalies. Many ore bodies lacked any surface expression, but further drilling and exploration revealed numerous ore deposits. The largest producing mines in the county are in this area and include the Colorado Lease 519, the Dickson-Snooper and Thorne 9 and 10, the First Chance and the Last Chance, the Mary L., Joan 2, Little Abner #1, the Picnic Tree, and Knob Hill. Extensive exploration and drilling have been carried on for the past several years with the result that recently, several larger ore bodies have been found with proven reserves of 30 million pounds of  $U_3O_8$ . The major discovery is the Hanson Ore Body belonging to Cyprus Mines. The companies involved in this exploration

effort believe that these deposits are the largest uranium deposits ever found in the Rocky Mountain province. This area should become the major uranium mining district of the state in future years.

Geologically similar to the Tallahassee Creek district is the High Park area. Only small prospects and developments are known within the area, but these are fairly numerous, and are currently being evaluated. The deposits lie in interbedded arkosic sandstone and conglomerate, shaly siltstone, and tuffaceous sediments. The deposits range from 4 to 13 ft in thickness and lie at depths of 4 to 80 ft. The average grade is generally less than 0.2 percent  $U_3O_8$ .

Other areas of interest include the Canon City Embayment, the Wet Mountain thorium district, and the Precambrian Granites near Cotopaxi. The uranium deposits in the Canon City Embayment are found in the Dakota Sandstone. Although they are fairly numerous, none large enough to warrant development have yet been found. The thorium occurrences of the Wet Mountains occur primarily to the south in Custer County, but some minor anomalies can be found in Fremont County. The Cotopaxi area contains small uraninite occurrences with minor autunite in veins in the mineralized shear zones in Precambrian granites. Some drilling has been done, but no development has followed.

The Texas Creek area is geographically close and geologically similar to the Cotopaxi area. There, the mineralization primarily occurs disseminated in the shear zones of both the Precambrian granites and Precambrian biotite gneisses. Uraninite, the primary uranium mineral, is found closely associated with fluorite and minor chalcopyrite. Although most of the mineralization is located in the shear zones, some minor anomalies and scattered uraninite grains can also be found disseminated throughout the nearby unshattered granite. Minor development work has taken place in this area, but no large ore bodies have been reported. The Lightning No. 2 is one of the larger prospects, and it is interesting to note that the mineralized zone plunges beneath a cover of volcanics that lie to the south.

The units with the most potential for uranium reserves within the county lie in the Tertiary fluvial arkosic and volcanic detritus of the Intermontane basins abutting the Thirtynine Mile volcanic field. The most promising of these lie in and adjacent to South Park and the Tallahassee Creek-High Park areas. These areas have produced in the past and have been shown to contain large reserves of uranium. The shear zones in the Precambrian granites and biotite gneisses near Cotopaxi, and the Dakota Sandstone in the Canon City area, however, should not be overlooked as potential areas, both because large deposits are known to occur in geologically similar strata in other parts of the state, and because proven uranium occurrences have already been found within these areas in this county.

### Picnic Tree Mine (Picnic Tree Claims - Hall Homestead)

LOCATION: SW1/4 sec. 26, T. 17 S., R. 73 W.  
 QUAD Black Mountain 15'  
 MAP PUEBLO  
 DVEL Open pits. Average depth to ore is 50 ft.  
 PROD During the period 1958-1967, a total of 13,525 tons of ore averaging 0.20% U3O8 and containing 52,776 lbs U3O8 were mined. Also, 2,222 lbs of V2O5 were recovered.  
 HOST Carbonaceous water laid tuffs and volcanic conglomerates in the Oligocene Tallahassee Creek Conglomerate.  
 MNZ Autunite has been identified. Uraninite (?) is also present.  
 DOI 1978  
 REF E. P. Beroni, 1978, Personal Communication. U.S. Geol. Survey, 1977, CRIB File. U.S. A.E.C., 1971, Production Records, Colorado.

### Pine Canyon Lode (Southmost Claim Group)

LOCATION: NW1/4 sec. 34, T. 49 N., R. 10 E.  
 LCRM The deposit is 100 ft south of the road in steeply dipping red beds. The CRIB file lists a deposit located on sec. 28, 29, 32, & 33, T. 49 N., R. 10 E. that occurs like this one. They are probably the same or connected occurrences.  
 QUAD Howard 15'  
 MAP PUEBLO  
 DVEL A 30 ft tunnel was driven along bedding. To 3 x background.  
 RNG The deposit lies in a black shale member of the Permian-Pennsylvanian red beds (possibly Maroon or Minturn Formations). The beds strike S8°E, and dip 42°NE. A volcanic intrusive lies about 100 ft off the radioactive prospect. Three radioactive black shale beds lie within 15 ft of the red bed section. A coal seam is also nearby.  
 HOST Malachite is associated with the radioactive black shales, along bedding planes and fractures. Assays of samples range from 0.006 to 0.016% eU3O8.  
 MNZ  
 DOI 1954  
 REF U.S. Geol. Survey, 1977, CRIB File. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Fremont County, Colorado.

### Rupp Property (Rupp Mine 39)

LOCATION: W1/2 sec. 18, T. 17 S., R. 70 W.  
 QUAD Cover Mountain 15'  
 MAP PUEBLO  
 DVEL There is one small open pit, approximately 100 x 70 x 30 ft; also, some drilling has been carried out.  
 PROD There is no record of production with the U.S. A.E.C.  
 BKG 150 cps  
 RNG 300 to 2000 cps  
 HOST The host is the Cretaceous Dakota Sandstone, primarily a lenticular layer high in the formation.

STRC There appears to be some relationship to fracturing and faulting. The deposit is on the west side of a shallow N-S striking anticline.  
 ALT There are abundant leached clay galls and ilmenite staining.  
 MNZ Autunite and carnotite occurs in clay seams and vugs, the vugs being the casts of plant debris. The uranium minerals are oxidized, and associated with manganese and iron oxide-stained, silicified fractures on the surface. The relationship of mineralization to the fractured rocks is not as obvious in the pit.  
 RMKS As of 1976, the property was being drilled by Rampart Exploration Company of Denver, Colorado.

## GARFIELD COUNTY

Production from Garfield County is large. The county is approximately fifth in production in the state. As of 1971, 394,134 tons of ore had been mined containing 553,444 lb of  $U_3O_8$ , and 11,928,419 lb of  $V_2O_5$ .

Garfield County, which lies in westernmost Colorado, typifies much of the Colorado Plateau terrane with relatively flat-lying sedimentary beds covering most of the county. The eastern third of the county is structurally more complex and is dominated by the Grand Hogback Monocline and the White River Uplift. The extreme northeastern part of the county is surfaced by Late Tertiary and Quaternary andesites and basalt flows that form the Flat Tops, a mountainous area now designated as Flat Tops Wilderness Area.

Nearly all the county's uranium production came before 1954. A total of about 394,000 tons of uranium-vanadium ore was mined, and most of that came from the Rifle and Garfield mines. The Rifle Mine yielded 387,613 tons of that ore, and the Garfield Mine produced 6,230 tons. Both mines are situated on extensions of the same ore body. One source estimates at least 50,000 tons of ore still are in reserve at the Rifle Mine. A mill at Rifle processed the ore from the mines and still operates as a secondary recovery system for vanadium from Uravan mineral belt ores. Plans are in progress to reactivate the plant as a uranium mill.

The Rifle Mine and the Garfield Mine are the most important occurrences in the county. Mines in the Rifle district and most other occurrences in the county lie in the Jurassic Morrison and Entrada Formations, and Triassic-Jurassic Navajo Sandstone, or the Triassic Chinle Formation. The largest mines (including the Rifle and Garfield mines) all produce from the Entrada Sandstone, with minor extensions into the Morrison Formation or the Navajo Sandstone. An interesting occurrence, different from any of the other known occurrences in the county, was discovered in a test well that was drilled for oil. The Schulte 1 occurrence is a highly radioactive black shale horizon in a 1-ft-thick alternating shale-quartzite zone near the base of the Cambrian Sawatch Quartzite. The major drawback, for this area at least, is that the deposit lies at a depth of 8,455 ft. However, it is similar to occurrences found near Burns and State Bridge in Eagle County. This enlarges the area of these unconformity-type occurrences and makes them more interesting exploration targets.

Favorable beds with high potential in the county include the Morrison Formation, the Entrada Sandstone, the Navajo Sandstone, and the Chinle Formation. These beds are all known to contain uranium and vanadium deposits, both in this county and in the Colorado Plateau in general.

## Rifle Mine (Rifle Creek Mine, Oriole Claims, and North Star Claims)

LOCATION: NW1/4NE1/4NW1/4 sec. 35, T. 4 S., R. 92 W.  
 QUAD Rifle Falls 7 1/2'  
 MAP LEADVILLE  
 DVEL The occurrence was discovered about 1909, and mining began around 1922. Little production has taken place since 1954, although the CRIB File estimates that there are probably at least 50,000 tons of ore still in reserve. The deposit was mined for 7,000 ft along the trend of the ore.  
 PROD As of 1971, 387,613 tons of ore had been mined at grades of 0.07% U308 and 1.51% V205, producing 545,260 lbs of U308 and 11,728,996 lbs of V205.  
 HOST The mineralization is primarily in the Jurassic Entrada Sandstone, and the Triassic-Jurassic Navajo Sandstone Formation.  
 STRC The Grand Hogback and several other sets of eastward and northwestward trending faults are prominent in the area, but these do not have any apparent control over the ore deposition. The faults are all post-ore, and offset the veins.  
 MNZ The primary minerals in the deposit are micaceous vanadium silicates (roscoelite) and montroselite, with some carnotite, tyuyamunite, galena-clausthalite, bayleyite, and mariposite. The ore occurs in three tabular layers (Nos. 1, 2, 3) each of which is bounded on one side by a thin (1/8 in.) layer of 4 galena-clausthalite, which is in turn bordered by a 11 to 2 ft layer of greenish sandstone containing a micaceous chromium - bearing mineral. These galena - clausthalite and chromium - bearing layers lie about No. 1 and No. 3 veins, but below No. 2 vein. If the veins were connected they would form an "S" shaped curve.

of 0.10% U308 and 1.67% V205 had been mined,  
producing 6 lbs of U308 and 100 lbs of V205.

HOST The host is probably the Jurassic Morrison  
Formation.

DOI 1971

REF U.S. A.E.C., 1971, Production Records, Colorado.

## GILPIN COUNTY

Production of uranium from Gilpin County has been small in spite of the fact that the county was the first uranium mining district in the U.S. A little over 400 tons of ore was shipped between 1871 and 1960, and most of that was high-grade, hand-sorted ore mined for its radium content. Production noted after the AEC began to keep records amounted to 49.25 tons, which yielded 391 lb of  $U_3O_8$ .

Gilpin County is located in the north-central Colorado Front Range. Precambrian schists and gneisses of the Idaho Springs Formation are exposed throughout the county. Extensive bodies of granite, granite-gneiss, quartz-monzonite gneiss, and granite pegmatite intrude the Idaho Springs Formation.

The first pitchblende in the United States was found in Gilpin County on the dump of the Wood Mine in 1871. As a result of the Curies' work with this ore in Paris, the area attracted many uranium (radium) prospectors.

The uranium occurrences in Gilpin County are found in metal mines of the Front Range mineral belt in the Central City district, largely in the Quartz

Hill area. The two largest producers were the Wood Mine and the Carroll Mine. The mineralization occurs in Tertiary veins that cut Precambrian metasediments of the Idaho Springs Formation. In most, if not all, of the mines in the district, the pitchblende is concentrated in small, discontinuous pods and stringers in fissure veins. The uranium is subordinate to base- and precious-metals, which have been actively mined in the district. None of the known uranium occurrences are economically mineable for uranium under current market conditions.

Gilpin County probably does not have a great potential for future uranium mining in the known mining districts within the mineral belt. Major deposits of uranium ore are found outside but near to the mineral belt in veins cutting garnet biotite gneiss and quartz biotite schists. Most of these veins and productive ore deposits occur in northeastward- and eastward-trending faults or fault zones. One such deposit is the Schwartzwalder Mine in Jefferson County. There is some minor potential for discovering similar deposits in parts of Gilpin County.

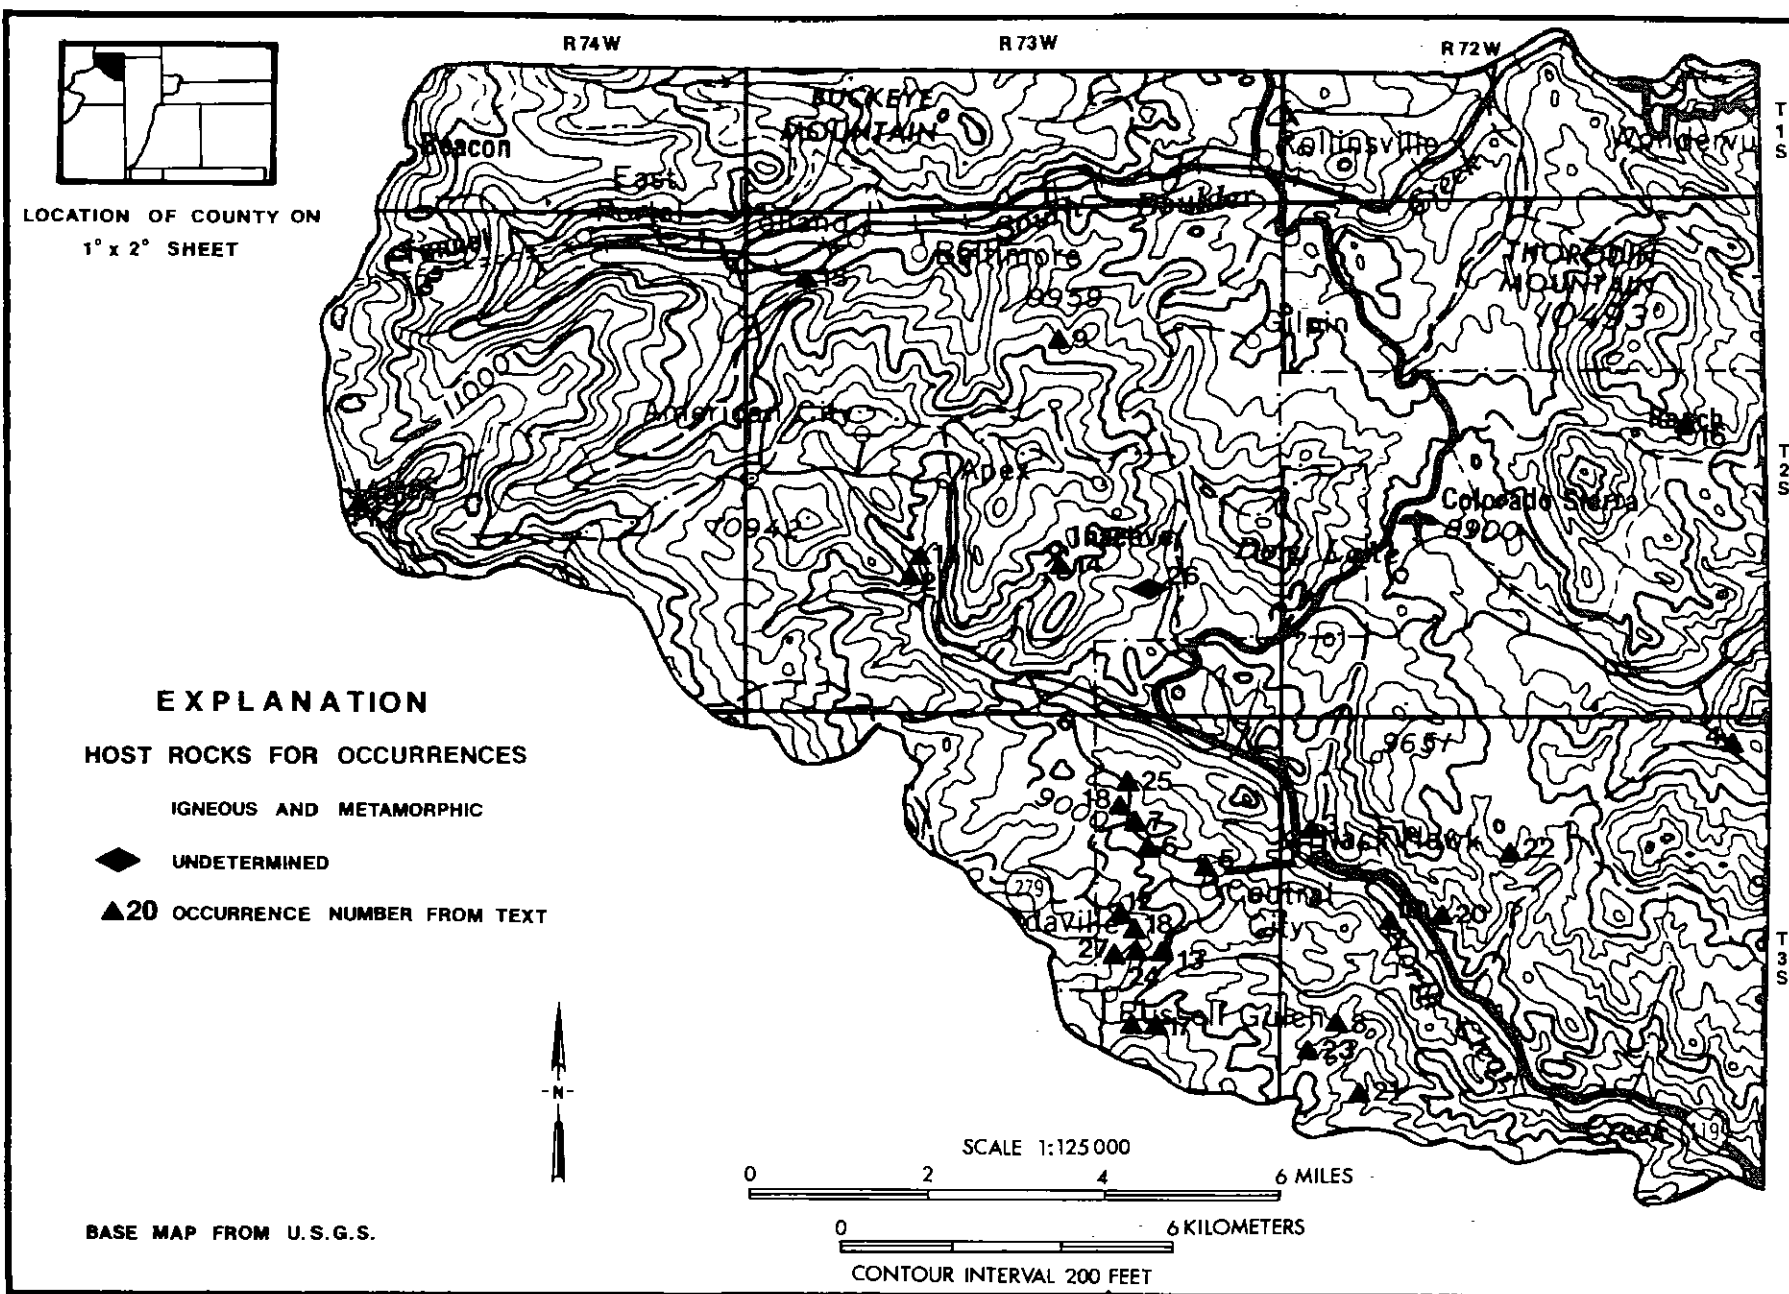

Figure 15. Radioactive mineral occurrences in Gilpin County, Colorado.

## Black Hawk 2 Claim

LOCATION: NW1/4 sec. 7, T. 3 S., R. 72 W.

QUAD Black Hawk 7 1/2'

MAP DENVER

DVEL There is a partly caved adit, and numerous pits and dumps.

BKG .02 mr/hr

RNG To .3 mr/hr

HOST The host is a Precambrian biotite schist of the Idaho Springs Formation.

STRC The schist is cut by a Tertiary quartz vein that strikes N30 - 35°E and dips S8°W. Its length is 500 ft, width is 2 ft, and its general shape is tabular.

MNZ Quartz and limonite are present in the vein. Autunite(?) coats fracture surfaces and is sparsely disseminated through the biotite schist. Samples collected range from 0.08 to 0.15% eU.

DOI 1954

REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Gilpin County, Colorado.

## Bowman Lease

LOCATION: NW1/4 sec. 1, T. 3 S., R. 72 W.

QUAD Black Hawk 7 1/2'

MAP DENVER

DVEL There are several old prospect pits in the area. This property had a pit 8 ft by 15 ft by 13 ft opened.

BKG .03 mr/hr

RNG To .6 mr/hr

HOST The host rock is a Precambrian granite gneiss of the Idaho Springs Formation. The rock in the pit is regolithic in appearance to a depth of 8 ft.

STRC A pronounced, iron-stained shear zone trends N70°W.

MNZ Limonite, hematite, and an unidentified black mineral (pyrolusite?) are present. The uranium mineral was not identified, but ore grade assays were obtained privately.

DOI 1955

REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Gilpin County, Colorado.

## Wood Mine (East Calhoun Mine, Calhoun-Wood)

LOCATION: NW1/4SW1/4 sec. 14, T. 3 S., R. 73 W.

QUAD Central City 7 1/2'

MAP DENVER

DVEL There was production for gold and silver.

PROD During 1953 and 1954, 18 tons were mined at a grade of 0.204% U3O8, containing 59 lbs U3O8.

HOST The host is a vein in Precambrian granite gneiss with quartz, biotite and microcline.

MNZ The mine was worked principally for gold and silver, and later on a smaller scale for uranium. Pitchblende, galena, and sphalerite were all found.

RMKS The first discovery of pitchblende in the U.S. was in 1871 on the dump of the Wood Mine.

DOI 1950

REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. Geol. Survey, 1977, CRIB File. U.S. A.E.C., 1971, Production Records, Colorado. Sims, D. K., and others, 1963. Drake, A. A., Jr.,

## GRAND COUNTY

Uranium production from the county has been limited. Records show that by 1971, 218 tons of ore had been mined, and 837 lb of  $U_3O_8$  were recovered. Excellent potential exists for more reserves to be found within the county.

The county is bounded on the west by the Park Range and on the east by the Front Range. Middle Park covers the rest of the county between the two ranges. Precambrian granites, gneisses, migmatites and minor basin rocks comprise the cores of the two ranges. Middle Park is an intermontane basin filled with recent sediments. The county lies north of the mineral belt, and uranium is the only mineral that has been produced in any quantity.

The three deposits that have produced uranium in Grand County are the Alaska-Humes Group, CPJ Claims, and Undecided Claims. The Alaska-Humes Group, located near Rabbit Ears Pass, produced ore from the Cretaceous Dakota Sandstone. The ore occurred as discontinuous pods or lenses of carnotite(?) in the sandstone, associated with carbonaceous layers.

The CPG Claims are located near the town of Hot Sulphur Springs. The property produced from the Coalmont Formation at the point where the formation rests on eroded Boulder Creek Granite and may be an unconformity-related type of occurrence.

The Undecided Claims, also known as the Beaver Group, lie near the town of Hot Sulphur Springs and are found in the Coalmont Formation. The mineralization, which is very similar to that at the CPG Claims, not only is associated with the contact between the Coalmont and the Boulder Creek Granite, but also is found in cracks and joints in the granite.

Potential for reserves to be found in the county is very good. Of the ten different rock types containing occurrences, those having the greatest potential are the Tertiary Troublesome Formation for sandstone-type occurrences; the basal Coalmont Formation, which may contain sandstone or unconformity-related types; and the Precambrian Idaho Springs Formation which contains occurrences that may be contact-metamorphic or anatectic.

REF Nishimori, and others, 1977. Young, and Hauff, 1975. Ludwig, and Young, 1975.

## GUNNISON COUNTY

Uranium production from Gunnison County has been large relative to most other counties in the state. By 1971, 8,679 tons of ore had been mined that contained 72,557 lb of  $U_3O_8$ . Excellent potential exists for more reserves in the county.

The geology of the county is quite diverse. Extrusive and intrusive rocks of the Elk Mountains dominate the northern part of the area. The Sawatch Range with its Precambrian rocks, Tertiary Intrusives, and interspersed lower Paleozoic rocks lies along the eastern side. Precambrian, lower Paleozoic and Tertiary extrusives are found along the valley of the Gunnison River which flows generally westward through the center of the county. The San Juan Mountains extend into the southern panhandle of the county, exposing Precambrian alkalic rocks in the Powderhorn area and Tertiary extrusives farther south.

The three deposits in the county that have produced uranium include Big Red 22, Brown Derby Mine, and Little Indian 36. The most important producer (95 percent of total) within the county is the Little Indian 36 Mine. Production from this deposit totaled 8,679 tons of ore and 7,762 lb of  $U_3O_8$ . The Little Indian Mine, located in the Marshall Pass uranium

district, is associated with the Chester Fault and lies near the Pitch Mine in Saguache County. Production from the Little Indian was from a vertical dipping zone in the Ordovician Harding Quartzite. The most abundant ore mineral was uranophane.

Potential for more reserves to be found within the county is very good. The Cochetopa and Marshall Pass areas show favorable potential for new reserves, especially along extensions of ore bodies from the uranium-producing area in Saguache County. Another very important type of radioactive occurrence is found in the Powderhorn region where thorium, with uranium in subordinate amounts, is concentrated in veins within Precambrian rocks. Powderhorn is one of the two thorium districts in the state; the other is in Custer County. These are also two of the few thorium districts in the United States. If the demand for thorium increases drastically in the future, Powderhorn will become a major area of exploration for, if not production of, thorium. The alkaline rocks of this district are now being studied in conjunction with potential uranium resource rocks throughout the world. (See Murphy, M., and others, 1978, Uranium in Alkaline Rocks, U.S. Department of Energy, GJBX-(78)78, 185 p. which was published as this publication went to press).

## Brown Derby Mine

LOCATION: NE1/4 sec. 3, T. 49 N., R. 3 E.  
 LCRM SE1/4 sec. 34, T. 49 N., R. 3 E. is also covered by claims. The mine is east of Quartz Creek.  
 DVEL An open cut with an inclined shaft and underground workings.  
 PROD In 1944, 400 tons of finished lepidolite and microlite containing 4,000 lbs of Ta2O5 and 238 lbs of U308 were produced.  
 HOST Large zoned pegmatite in a Precambrian meta-diorite. Three parallel dikes strike N10° - 45°E and dip 20°-30° to the southeast. Dikes are 11 ft wide and extend for as much as 1,300 ft. Average distance between dikes is 75 ft.  
 MNZ Quartz, microlite, lepidolite, topaz, albite, beryl tourmaline, muscovite, minor biotite, magnetite, monazite, and columbite. Uranium is associated with the microlite. Hand samples assayed 5.44% to 6.04% U308.

## HINSDALE COUNTY

Production from this county has been extremely small. Between 1958 and 1961, 18 tons of ore were mined that yielded 68 lb of  $U_3O_8$ . Potential for more reserves in the county is also small.

The county is entirely within the San Juan Mountains uplift. This uplift and the accompanying Tertiary volcanic activity resulted in extensive extrusive and intrusive rocks. Along the southern edge of the county Paleozoic and Mesozoic rocks dip away from the uplift and into the San Juan Basin. The volcanic activity created several large volcanic caldera systems that contain important producers of base and precious metals within the county.

The one producer of uranium in the county was the Beth Group, located in the northwestern part of the county north of Henson Creek. Production was

from veins and disseminations in a fractured rhyolite porphyry stock that had intruded the Tertiary volcanic rocks. This intrusive stock is one of a series that forms a belt 1.5 mile wide and 8 miles long. Fifteen uranium occurrences have been reported in this belt, but they are not documented.

The potential for uranium reserves within the county is low. The volcanic rocks that cover most of the county are not considered favorable hosts for uranium deposits. However, some deposits are known in volcanogenic rocks, but they will require more study. The belt of rhyolite intrusives that contain the Beth Group has the highest potential for reserves. A major company has explored the claims but has taken no action.

## HUERFANO COUNTY

Production in the county has been small. Records show that 517 tons of ore were mined, but only 33 lb of  $U_3O_8$  were produced. This low yield was due to the fact that a large amount of the mined ore was not amenable to processing methods at the time. Still the potential for reserves to be found in the county is high.

Complicated structures and varied rock types characterize the geology of the county. Precambrian rocks are exposed in the Sangre de Cristo and Culebra Ranges on the west side and in the Wet Mountains on the north side. A full section of Paleozoic through Cenozoic rocks are exposed on the sides of the ranges and in the Raton Basin. The famous Spanish Peaks, remnants of Middle Tertiary intrusives, lie on the border between Las Animas and Huerfano Counties.

The three deposits that have recorded production are Anal No. 1, Badito Cone, and Columbine Hills. The Anal No. 1 Deposit produced from beds within the

Tertiary Farasita Conglomerate. Although many occurrences are known in the Farasita Conglomerate, this is the only deposit that produced any uranium.

Badito Cone, or Stumbling Stud Pit as the mine is known, is on the south side of the Badito Cone phonolite intrusion. Production at the site has come from inliers of the Cretaceous Dakota and Jurassic Morrison Formations. The mined ore yielded no  $U_3O_8$  because the uranium was chemically bound to a refractory mineral. Dark purple fluorite and metallic zirconium are associated with the uranium.

The last producer is the Columbine Hills Property, for which no location is known. Only one ton of ore was mined from this property.

High potential exists for new reserves of uranium in this county. The Farasita Conglomerate is the most favorable unit in the county and would contain sandstone-type occurrences.

## Badito Cone (Stumbling Stud Mine)

LOCATION: sec. 20, T. 26 S., R. 68 W.

QUAD Badito Cone 7 1/2', Hayden Butte 7 1/2'

MAP TRINIDAD

DVEL Production was all from the Dakota Sandstone.

PROD The U.S. A.E.C. Preliminary Reconnaissance Reports show that 510 tons were mined at a grade of 0.13% U3O8 and 0.009% V2O5.

HOST The mineralization occurs as veins and disseminations in a Tertiary rhyolite intrusive and Cretaceous Dakota Sandstone and Jurassic Morrison Formation.

STRC The intrusion is in the crest of the Greenhorn anticline.

ALT The sandstone is baked and silicified and contains abundant fluorite.

MNZ The mineralization is associated with fluorite and metallic zirconium. Uranium mineral possibly coffinite. The rhyolite has an average value of 12 ppm (U).

## JACKSON COUNTY

The production of uranium from Jackson County has been small-- only one deposit has produced ore. The total production to 1971 is reported as 500 tons at a grade of 0.30 percent, producing 3,000 lb of  $U_3O_8$ .

The central part of the county is dominated by North Park, a large intermontane basin filled with Tertiary sediments and volcanics. North Park is bounded on its eastern and western edges by the Medicine Bow Mountains and the Park Range, respectively. Mesozoic and Paleozoic sediments flank the Precambrian granites and gneissic cores of the ranges.

The one producer in the county is the Pedad Claims, located in the northwestern part of the county near

Mount Ethel. They produced ore from a breccia zone in the Precambrian Mount Ethel Granite. A primary mineral associated with the uranium was dark purple fluorite.

It is interesting to note that all occurrences in the county are in the northwestern part of the county. Vein-type occurrences are the most abundant reported, and 11 of these lie in a small area. There is potential for more vein-type and sandstone-type reserves to be found within the county. The large area of the North Park basin could contain sandstone type occurrences of important size. Although exploration activity has been sporadically intense in North Park for a number of years, no occurrences are documented from these efforts.

## JEFFERSON COUNTY

Jefferson County has been a major county for production of uranium in the state. The Schwartzwalder Mine, one of the major vein-type uranium mines in North America, has produced approximately 98 percent of all  $U_3O_8$  in the county. As of May 1978, total production from the mine has been reported as 10,500,000 lb of  $U_3O_8$  (J. Haley, 1978, pers. comm.), which makes the Schwartzwalder the largest uranium producing mine in the state. Twelve other mines in the county have produced uranium, but only a small percentage compared to the Schwartzwalder's total production. By 1971 these other mines had produced 39,781 tons of ore and 210,827 lb of  $U_3O_8$ . The potential for more reserves of uranium to be found in the county is excellent.

Two different terranes characterize the geology of Jefferson County. The northeastern quarter of the county is underlain by Paleozoic and Mesozoic sedimentary rocks, usually flat-lying, except near the mountain front. The rest of the county is composed of Precambrian granites, gneisses, and schists of the Front Range, mainly the Idaho Springs Formation and the Pikes Peak Granite, which are cut by many northwest-southeast-trending faults, fault zones, and/or breccia reef systems.

Many occurrences in the county can be considered important; however, only the following major producers are discussed: Ascension Mine, Aubrey Ladwig Mine, Grapevine Mine, Mann Ranch, Mena Mine, Leyden Coal Mine, Pallaora Lease, Schwartzwalder Mine, Stone Placer Mine, and Wright Lease.

Seven of the ten mines occur where a fault or breccia zone transects the Precambrian Idaho Springs Formation. With the exception of the Leyden Coal Mine, the Mann Ranch and the Pallaora Lease, these mines, including the Schwartzwalder, are all clustered along three northwest-trending faults or breccia reef systems within six miles of the fault system along the mountain front.

The Mann Ranch and the Pallaora Lease lie close to each other on the hogback of the Dakota Formation at Turkey Creek Canyon. Faulting in the Dakota Sandstone appears to have dammed up the mineralizing solutions that formed both deposits. Asphaltite and uraninite are the ore minerals.

The Leyden Coal Mine is the final type of important deposit in the county. At this mine the uranium occurs as uraninite in silica-filled cracks and fractures within the coal. During the 1950's the U.S. Geological Survey carried out a drilling program at the mine and reported an estimated reserve of 17,000 tons of ore at a grade of 0.2 percent  $U_3O_8$ .

As pointed out earlier the county has high potential for more reserves of uranium. The Precambrian fracture-controlled type of deposits, the most likely to be found, will be explored for in the foothills west of the mountain front. The sandstone type of deposit has less potential.

## Aubrey Ladwig Mine (Aubrey Ladwig Lease, Gary Mine)

LOCATION: SW1/4 sec. 18, T. 3 S., R. 70 W.  
 LCRM Access is from Colorado 93 via Cressmans Gulch.  
 QUAD Ralston Buttes 7 1/2'  
 DVEL Mineralization was discovered in 1954. Production began in 1955. Workings consist of an open pit, shaft with a crosscut and stope, and various exploration pits.  
 PROD During the period 1955-1956, 1,942 tons of ore were mined at a grade of 0.25% U308, producing 9,527 lbs of U308.  
 HOST Brecciated garnetiferous biotite-quartz gneiss and pegmatite of the Precambrian Idaho Springs Formation.  
 STRC Mineralization in fractures or coarse brecciation along or near the contact of the pegmatite and gneiss.

MNZ Lenses and pods of pitchblende up to 60 pounds in weight were mined in the open pit. Meta-autunite was also common. Metatorbernite, metazeunerite, and fourmarierite have also been identified from the mine. Pyrite is common but no base metal sulphides have been identified. Fluorite has been identified from the mine.

RMKS This occurrence is not on a breccia-reef fault, which makes it different from others in the area.

## Schwartzwalder Mine (Ralston Creek Mine)

LOCATION: SW1/4 sec. 25, T. 2 S., R. 71 W.

QUAD Ralston Buttes 7 1/2'

DVEL Mine was discovered in 1949. Production began in 1953. The mine was sold to the Denver - Golden Oil and Uranium Co. and subsequently to the Cotter Corporation, the present owners. As of 1978, mining was being carried out on the 1600 level, and exploration was being done on the 1900 level of the mine. The Schwartzwalder Mine is one of the major producers of the uranium in North America from a vein type environment. Through 1966, the U.S. A.E.C. had purchased 137,267 tons averaging 0.79% U308, and containing 2,166,772 lbs of U308. In Young, 1977, total production to date (1977) is reported as approximately 9.6 million lbs of U308, with the grade of ore about 0.6% U308. As of

# JEFFERSON COUNTY

*Not seven devils  
May actually be from Bonzo!*

June, 1978 total production is reported as about 10,500,000 lbs of U3O8. Grade of ore being mined in 1978 is approximately .35% U3O8.

HOST The mineralization occurs in garnet biotite gneiss, quartz biotite schist and quartzite, all which are within the Precambrian Idaho Springs Formation (hornblende gneiss).

STRC Large NW trending faults adjacent to the NW Rogers breccia-reef fault system, especially horsetails or cymolds in these faults, controls the mineralization.

ALT Chloritic and potassic alterations are confined to the breccia fragments along with silification, and replacement by ankerite. Zoning has not been recognized.

MNZ Uraninite is the primary mineral in the deeper levels. Sooty pitchblend occurred in the upper levels. Other minerals present are pyrite, chalcopryite, tetrahedrite, bornite, galena, sphalerite, molybdenite in quartz, ankerite, calcite and potassic feldspar gangue.

RMKS For the best overview of the mine read Young, E. J., 1977, and Sheridan, D. M.; and others, 1967.

## KIOWA COUNTY

Kiowa County is situated in the eastern prairies of Colorado. Surface formations exposed are primarily the Miocene-Pliocene Ogallala Formation and the Upper Cretaceous Niobrara Group. Some Upper Cretaceous Pierre Shale crops out near the eastern borders of the county.

No production of uranium has taken place in this county, and no occurrences are known within the county.

Several wells in the county sampled by the U.S. Geological Survey, however, showed higher than average values of uranium in the water.

North of the Arkansas River, the Ogallala Formation, which generally had higher than average uranium values in water samples, may be an interesting area for further study and has some potential for uranium resources in a sandstone-type of occurrence.

## KIT CARSON COUNTY

Kit Carson County is located in extreme eastern Colorado and covered almost entirely by the rocks of the Miocene-Pliocene Ogallala Formation. Some small exposures of the Upper Cretaceous Pierre Shale are present along the upper course of the Republican River.

No uranium occurrences are known within the county, but favorable formations with uranium resource potential

are present. Water sampling in other parts of the eastern plains has shown higher than average uranium values in waters derived from the Ogallala Formation. The Sharon Springs Member of the Pierre Shale is also known to contain small occurrences of uranium in other parts of the state as well. Due to the flat topography of the county, water sampling would be the most desirable method of exploring for uranium.

## LAKE COUNTY

No uranium has been recorded from the county, and no important occurrences are known within the area.

Lake County lies in west-central Colorado in an area of rugged mountainous terrain. The basement rocks are primarily Precambrian schists, gneisses, and granite. Both the igneous-metamorphic rocks and the overlying Paleozoic sedimentary rocks are intensely folded and faulted, and are intruded by Late Cretaceous(?), Tertiary, and Pleistocene(?) sills, dikes, and plugs. Pleistocene glaciers have shaped the present stream valleys and mantled much of the area with thick surficial debris.

Small quantities of uranium minerals are nearly ubiquitous throughout the various metal deposits in the county, but the only concentrations found so far have been in the St. Kevin district. Many of the

old prospects and mines in that area show slightly higher than average background, but only a few show twice background or more. The radioactive minerals are not megascopically identifiable but are generally associated with limonite or other iron oxides that are found in a fine-grained, probably granitized and disintegrated schists. Torbernite is occasionally associated with turquoise in some of the turquoise mines in that district.

The county probably does not hold great potential as a uranium province. Underground exploration in existing mines and thorough surface prospecting have not resulted in any important discoveries. In the Alma mining district, just east of Lake County, uranium occurrences are present, but they, too, are scattered and weak. What uranium is present appears to be simply a minor constituent of metal-sulfide deposits.

## LA PLATA COUNTY

Production of uranium from La Plata County has been very limited. Records show that by 1971, 687 tons had been mined that yielded 1,029 lb of  $U_3O_8$ . Potential is good that more reserves of uranium may be found in the county.

La Plata County is on the southwestern edge of the San Juan Mountains, and it falls into two geological structural areas--the San Juan Uplift on the north, and the San Juan Basin on the south. The San Juan Uplift has exposed Precambrian rocks in the northwestern area, such as the Needles Mountains. Associated with the uplift are the intrusive rocks of the La Plata Mountains complex, a small uplift in the northwestern corner of the county. Sheetlike igneous bodies and sills have intruded Upper Paleozoic sediments. The San Juan Basin is a large sediment-filled basin that extends into New Mexico wherein lie 50 percent of the uranium reserves of the United States. The Grants Mineral Belt contains sandstone-type deposits in the Jurassic Morrison Formation.

The four deposits which have produced uranium include Black Hawk, Good Hope-Nevada Group, Lucky

Lepracon, and Shorty Lode. Two of these producers, the Black Hawk and the Lucky Lepracon are unlocatable. The most important producer in the county is the Good Hope-Nevada Group, which accounts for 95 percent of all tonnage and produces ore from the Entrada Sandstone. The deposit is part of the Entrada roscoelite belt, which includes the Graysill Mine in San Juan County, the mines around Placerville, San Miguel County, and the Rifle Mine in Garfield County. Roscoelite occurrences in the Entrada Sandstone yield principally vanadium with uranium as a by-product.

The potential for more reserves to occur in the county is good. Uranium occurrences are reported over a 36-sq-mi area around Thunder Mountain in the Needle Mountains. This area has favorable potential for vein type occurrences, although environmental problems must be addressed. More reserves of the Entrada roscoelite-type may occur in the Entrada Sandstone in the northwestern part of the county. Lastly, the San Juan Basin in the southern part of the county has potential for sandstone-type occurrences.

## LARIMER COUNTY

Minor production of uranium reported within the county totals about 791 tons that contained 4,144 lb of  $U_3O_8$ . A few tons came from rare-earth and uranium-bearing pegmatites and from small occurrences in the Dakota Sandstone. The rest, 633 tons, came from the Copper King Mine at an average grade of 0.30 percent  $U_3O_8$ , containing 3,771 lb of  $U_3O_8$ . Potential is moderate for more reserves to be found.

Larimer County lies in north-central Colorado, straddling the Rocky Mountain and Great Plains physiographic provinces. The western three-quarters of the county are dominated by the Precambrian mountains of the Front Range and the Medicine Bow Mountains. The Precambrian rocks are primarily metamorphosed sedimentary rocks, intruded by granites and other related igneous masses. In the eastern section of the county the formations range within a very short distance from Paleozoic to Late Cretaceous in age. The sedimentary formations are upturned along the edge of the Front Range, but are relatively flat-lying eastward onto the plains.

By far the most important known occurrence of uranium in Larimer County is at the Copper King mine, discovered to contain uranium ore in 1949. It was one of the initial vein-uranium discoveries in the Front Range outside the Colorado mineral belt. Two major types of mineral deposits are present at the mine: 1) a skarn containing pyrometasomatic massive sulfide-magnetite ore, and 2) uranium minerals in veins that cut the skarn. The sulfide ore is late Precambrian in age and includes pyrite, sphalerite, chalcopyrite, pyrrhotite, and some magnetite. The uranium ore is probably early Tertiary in age and includes uraninite, coffinite, and  $UO_3$ -rich pitchblende.

The rare-earth and uranium-bearing pegmatites are found in the Crystal Mountain district west of Loveland and Fort Collins, and in other areas of Precambrian terrane. The pegmatites are associated with late Precambrian granitic sills and dikes that intruded the older Precambrian metamorphics of the Front Range. Minor amounts of copper, beryl, mica, and gold were found in the Crystal Mountain district and have been mined sporadically since 1884. Uranium and rare-earth minerals were mined from the pegmatites during the late 1940's and early 1950's. A few small deposits of carnotite have also been found and mined to a small extent in the Dakota Sandstone along the Front Range.

Larimer County has potential for uranium reserves and resources both in Precambrian rocks and in sedimentary terrane. While uranium production from the pegmatites will probably remain small or nonexistent, other deposits in the Precambrian rocks similar to the Copper King Mine are likely to exist. Detection of these vein-type deposits is very difficult, and airborne scintillometer scans followed by ground reconnaissance are required to locate them. Because the Copper King vein was not exposed at the surface (the uranium ore was discovered on the dump of the old workings), similar undiscovered veins likely will lack surface expression. Complicating matters, the entire area is mantled by glacial deposits of generally unknown thickness. The Dakota Sandstone is the most likely sedimentary formation to contain uranium resources because small occurrences are known within it and because geologically similar deposits have been mined from the Dakota in other parts of the state.

RNG 300 to 10,000 cps  
HOST The host is a 15 ft x 250 ft Precambrian pegmatite body in a layered quartz-feldspar amphibole gneiss with aplitic fine-grained to pegmatite stringers. The foliation trends N15°E, dips + 75°SE.  
MNZ The mineralization is in the central part of the pegmatite in the form of a yellow secondary uranium mineral. There are no primary minerals. The radioactivity is associated with smoky quartz. The uranium mineral(s) coat grains and fracture surfaces, permeating some of the mineral grains. The hottest spots appear to be associated with biotite segregations.  
RMKS The pegmatite is zoned: a 2 ft outer zone is feldspar-rich, with large nine in. blades & books of biotite; the borders have a slight hematite stain. The inner zone is quartzose, graphic granite, with some barren, bull quartz.  
REF Charles Line, 1977, Personal Communication.

## Spring Claim ( Revis Claim, Unnamed Claim, Spring 1 Claim)

LOCATION: SE1/4NE1/4 sec. 15, T. 8 N., R. 75 W.  
LCST UNSURVEYED  
LCRM The site is near the Sleeping Elephant camp site on U.S. Highway 287.  
QUAD Boston Peak 7 1/2'  
MAP GREELEY  
DVEL A 13 ft deep prospect pit was sunk over the radioactive high. An area above the radioactive spring has been bulldozed, leaving a 200 x 100 ft flat area.  
PROD Approximately 40 tons of ore grade material was stockpiled on the surface.  
BKG .02 mr/hr  
RNG .3 to 2.5 mr/hr  
HOST The deposit is located at the contact of a very acidic Precambrian granite with a Precambrian biotite schist of the Idaho Springs Formation. There are small acidic pegmatites of pink feldspar phenocrysts up to one inch across, and quartz.  
STRC The mineralization occurs along fracture faces in the granite associated with the small pegmatites. A large shear zone cuts the area.  
ALT The granite has been sericitized and ilmonitized above the mineralization.  
MNZ Autunite and ilmonite could be megascopically identified and a yellow-green non-fluorescent uranium mineral was associated with the autunite. Chip and channel samples collected ranged from 0.021 to 0.032% eU308. A ilmonite precipitate at the nearby spring contains 0.045% eU308 and an associated hematite deposit contains 0.021% eU308. Sooty pitchblende was discovered on fracture faces in the bottom of the prospect pit. Mineralization appears to strike ± 70° to the south.

# LARIMER COUNTY

by E. C. Robinson for uranium exploration in 1954.

PROD According to the U.S. Bur. of Mines, during 1956, 100 tons of uranium ore at 0.17% U3O8 and 100 tons of 0.11% U3O8 were mined from Red Hill, with 50 tons of 0.48% U3O8 also mined from Uranium Queen. The U.S. A.E.C. Records show a total of 140 tons mined at a grade of 0.13% U3O8 and 0.01% V2O5, producing 340 lbs of U3O8 and 22 lbs of V2O5 prior to 1971.

BKG .1 mr/hr

RNG .2 to .3 mr/hr

HOST The host is Precambrian granite, porphyritic granite, and granite pegmatite.

STRC Vein structures are supposed to lie in the granite, but trenches have been cut along the structures and are filled with blasted rock. The radioactivity is associated with NW trending fractures. One fault which has been exposed by blasting strikes N35°E and dips S77 1/2°E.

MNZ Autunite, uranophane, gummite, uraninite, and pitchblende were found in both the stockpile and the dump. Values of samples taken range from 0.22 to 0.48% eU3O8. Along the fault lies a mylonitic zone which is mineralized with uranophane and autunite. Radioactivity count increases where the fault intersects the NW trending fractures.

## Wahketa Lease (Wahketa Mine)

LOCATION: sec. 18, T. 8 N., R. 69 W.

LCST UNCERTAIN

LCRM The P.R.R. indicates this is in sec. 13. The prospect is on the Dakota Sandstone rim, 1000 ft from the road across an irrigation ditch. The CRIB file lists this as sec. 13, T. 8 N., R. 70 W. A second CRIB reference verifies the location originally given above.

QUAD La Porte 7 1/2'

MAP GREELEY

DVEL The rim has been stripped at four places, with approximately 50 tons of rock broken.

PROD In 1955, six tons were mined at a grade of 0.07% U3O8, producing 8 lbs of U3O8, and 6 lbs of V2O5 at a grade of 0.05%.

RNG 0.06 to 0.7 mr/hr

HOST The deposit is in the lower Cretaceous Dakota Sandstone along the prominent hogback rim formed by the sandstone. The formation strikes northerly and dips 30° to the west.

STRC The hogback appears to be the west limb of an anticline, the center of which has been eroded away.

MNZ Mineralization of a carnotite type has been exposed at scattered points along the rim for approximately 0.2 miles. A weakly fluorescent mineral not distinguishable in ordinary light occurs in several of the pits.

RMKS An assay showed 0.16% U3O8. Autunite has also been identified.

## LAS ANIMAS COUNTY

Production from the county was as small as could be achieved, 1 ton mined which contained 1 lb of  $U_{38}$ . Potential for more reserves is minor.

A large part of the eastern Las Animas County is covered by the Lower Cretaceous Dakota Sandstone. Outcrops of other sedimentary formations are also found in that area ranging from the Permo-Triassic Lykins Formation to Tertiary and Quaternary(?) lava flows. The western part of the county, which involves more complex geology, is bounded on the west by the slopes of the Culebra Range of the Sangre de Cristo Mountains. Pennsylvanian and Permian sedimentary formations about these ranges, and progressively younger formations are found to the east. Around the Spanish Peaks in the northern area early Tertiary intrusives are found in the form of dikes, sills, and stocks.

Extensive Tertiary and Quaternary(?) lava flows cap several mesas along the southern edge of the county. The structural Raton Basin extends from New Mexico northward through the center of the county.

Several uranium occurrences are known within the county, predominantly around Trinchera Peak on the Costilla County line. One ton of ore was mined from the Virginia 14 Claim, but no other production has taken place within the county. Favorable units with potential include the Pennsylvanian and Permian continental sediments in the western part of the county, the Dakota Sandstone, the Morrison Formation, and the Purgatoire Formation. The majority of known prospects seem to lie in the Dakota Sandstone at its contact with the Purgatoire Formation. However, the potential of the county is very limited.

## LINCOLN COUNTY

Lincoln County lies in the central Great Plains of Colorado. Stream courses and watersheds have, in places, eroded through the extensive Ogallala Formation to expose the Upper Cretaceous Pierre Shale. The only major structure within the county is the Las Animas Arch, lying in the southeastern part.

Although no uranium occurrences are known within the county, some structures and formations warrant

inspection as to potential. Water sampling by the U.S. Geological Survey has shown higher than average uranium values in waters originating from the Ogallala Formation and from the Sharon Springs Member of the Pierre Shale. In addition, higher than average uranium values have been found in waters draining the north side of the Las Animas Arch.

## LOGAN COUNTY

No uranium production has been recorded in Logan County. One reported occurrence in the county appears to be in the Cretaceous Pierre Shale.

The county is underlain by a variety of flat-lying Quaternary, Tertiary and Cretaceous sediments of the Great Plains. Some slight potential for uranium resources within the county may be found in the outcropping

Tertiary Ogallala and White River Formations and in the subsurface Cretaceous Laramie Formation and Fox Hills Sandstone. These are all favorable for sandstone types of occurrences. Uranium deposits are being developed in the Laramie Formation in Weld County just west of Logan County, and these deposits could extend into Logan County.

Base from U.S.G.S.

## MESA COUNTY

Mesa County falls within the Uravan mineral belt, which has produced uranium since 1881. Vanadium has been an important coproduct of the uranium of this area. Production from the county from January 1, 1948 to January 1, 1978 has been 2,271,000 tons of ore mined producing 13,180,000 lb of  $U_3O_8$  at a grade of 0.29 percent. From these tons mined 2,266,000 tons were processed for vanadium producing 41,811,000 lb of  $V_2O_5$  at a grade of 0.92 percent.

Mesa County is in the sedimentary terrane of the western slope of Colorado. Most of the county is covered by Cretaceous, Jurassic, and Triassic rocks. A large part of the northeastern area of the county is covered by Tertiary sediments and volcanics. The

Salt Wash Member of the Morrison Formation is the most important host rock for the uranium deposits within the county. Deposits occur within it as pods and "rolls" in channels within the sandstone.

Many active and inactive mines are located on mesas flanking the Dolores River. All of the production from the Uravan mineral belt comes from the southwestern part of the county, near the community of Gateway and farther south. Reserves in the county are large, and the potential for more to be found is excellent. It will be a major producer for years to come. Abundant literature has been written on this area, and those seeking more information are referred to the Mesa County cross-index in Volume 2.

## MINERAL COUNTY

No reported occurrences of uranium have been noted in Mineral County. The potential for reserves to be located within the county is small.

The county is almost entirely underlain by Tertiary volcanic rocks of the San Juan Mountain Uplift. These rocks are related to the volcanic calderas in and near the county, including the Bachelor, Creede, La Garita, and San Luis Calderas.

There is little probability that uranium reserves will be found in the county. However, the type that is the most probable to be found is associated with sediments or tuff in and around caldera systems. This type of occurrence is important in Mexico, but more research needs to be done on them.

## MOFFAT COUNTY

Uranium production from the county totals about 1,627,354 tons of ore, with an average grade of 0.13 percent  $U_3O_8$ , making it one of the largest producing counties in the state. The potential is very good for more reserves to be found.

Moffat County is situated in the northwestern corner of Colorado. Much of the county is topographically relatively flat, with two major exceptions. The first are the Elkhead Mountains, which represent erosional remnants of a Tertiary volcanic field that once covered the northeastern part of the county. Secondly the Uinta Mountains, with their Precambrian core, extend into the northwestern corner from Utah. The Uinta Arch and the Axial Basin Anticline traverse the county diagonally from northwest to southeast, dividing it nearly in half. Although other formations ranging in age from Cambrian to Pliocene are exposed locally, the Eocene Wasatch Formation and the Miocene Browns Park Formation mantle the majority of the county. Those formations directly overlie a regional unconformity and are the hosts for most of the uranium deposits and occurrences within the county.

The most important uranium occurrences are found in the Maybell district in the Browns Park Formation, a tuffaceous sandstone of continental origin. The major deposits in this district lie on the flanks of the Lay syncline, a large, shallow, east-trending structure. The largest deposits are found in sandstone, but a conglomerate at the base of the Browns Park Formation is also anomalously radioactive throughout the area. Small faults common within the district appear to have localized the ore to some degree. Both oxidized and unoxidized rocks contain ore. In the oxidized sandstones the ore is yellow, primarily due to iron oxides. The most common uranium minerals of oxidized ore are meta-autunite and uranophane. The unoxidized ore is gray or bluish due to finely divided pyrite, and the dominant uranium minerals are coffinite and uraninite. The five largest producing mines of this district are the Rob Rollo Mine, the Marge Mine, the Gertrude Mine, the Sage-Buella Mine, and the Johnson Lease, in that order.

The five properties in the Maybell district produced 1,621,780 tons of ore from the Browns Park Formation. The remainder was reported from other properties in the Maybell district and from the Skull Creek district. Although the Maybell district was inactive for many years, a number of the old mine workings have been reactivated, and additional new development is now taking place. The ore is now being heap-leached, and about 200,000 lb of  $U_3O_8$  ore is being produced yearly. The Skull Creek district is not presently active.

Areas with potential within the county will be those mantled by Browns Park Formation because of the size and features of the known deposits in that formation. Small occurrences are also reported from the Morrison Formation, Wasatch Formation, Entrada Sandstone, Curtis Formation, Carmel Formation, Iles Formation, Weber Formation, and Chinle Formation. Of those, the Wasatch Formation, because of its areal extent and numerous reported small occurrences, would appear to be the next most potential unit for uranium reserves. It should be noted, however, that large deposits are known within some of the other formations mentioned, but in other parts of the state and in Utah. The nearest and most important of those include deposits in the Morrison Formation, the Entrada Sandstone, and the Chinle Formation. These, plus several of the other formations containing occurrences are exposed along the scarp of the breached Skull Creek Anticline. This anticline, lying on the southeast edge of the Uinta Uplift, shows marked geochemical anomalies of several economic minerals, including uranium. The Skull Creek district lies on the southeast edge of the anticline and probably represents one area of concentrated mineralization. Based on the extensive geochemical anomaly and alteration of rock units, other such mineralized areas could exist along the flanks of the anticline or at depth. The area near the Tertiary Intrusives in the northeast could also be favorable.

CRAIG  
As of 1971, one ton of ore was mined from Cedars Claim No. 1 at grades of 0.20% U3O8 and 0.05% V2O5, which produced four lbs of U3O8 and one lb of V2O5.

BKG .02 mr/hr  
RRG .05 to 1.2 mr/hr  
HOST The host is the Miocene Browns Park Formation. The maximum radioactivity (1.2 mr/hr) was found in a ten in. bed of gray to yellow, fine- to coarse-grained, poorly-cemented sandstone. Thin layers of ilmonite-stained sand showing disseminated flakes of carbon (hydrocarbons?) were noted. A few ft below the radioactivity horizon a bed of sandstone with a thin layer of gypsum was noted. A few thin lenses of conglomerate of varied size, composition and stratigraphic position occur in the area. Most of these beds exhibit cross bedding of varied intensity.

STRC The anomalous radioactivity is found in a northwest-southeast-trending breccia zone. It averages three ft wide.

MNZ There are abundant yellow unidentified uranium minerals coating the sandstone and quartzite fragments.

DOI 1956  
REF U.S. Geol. Survey, 1977, CRIB File. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1971, Production Records, Colorado. Finch, W. I., 1967. U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado. U.S. Geol. Survey, 1956, TEI-423, p. 29.

## Biles' Shaft

LOCATION: sec. 31, T. 4 N., R. 100 W.

LCRM Directions to the deposit are given as follow: "From Vernal, Utah, at intersection of U.S. Highway 40 and Utah State Highway 44, drive east on U.S. Highway 40 for 57.2 miles; turn left through steel gate and drive 0.3 mile, right 0.4 mile to Biles' Shaft."

QUAD DVEL  
Skull Creek 7 1/2'  
A ten-ft shaft was sunk for exploratory purposes at the site of a drill hole that encountered weak mineralization.

HOST The mineralization occurs near the Jurassic Curtis-Entrada contact, and probably lies in the upper part of the Entrada Sandstone. The host is a gray, medium-grained, friable sandstone containing carbon less than one in. thick along some bedding planes. There is some ilmonite staining on fractures and bedding planes.

STRC The prospect is on the south flank of the Red Wash anticline. The beds strike N47°W and dip 60°S. There is a conspicuous fracture that cuts the bedding at approximately 90°, but it has no obvious relationship to mineralization.

MNZ The mineralization is associated with the carbonaceous material in the sandstone, but no uranium minerals are megascopically visible.

DOI 1955

LCRM This deposit is located in the Washakie Basin.

PROD As of 1971, one ton of ore was mined at grades of 0.15% U308 and 0.20% V205, producing 3 lbs of U308 and 4 lbs of V205.

HOST The host is the Wasatch Formation.

DOI 1971

REF U.S. A.E.C., 1971, Production Records, Colorado.

## Cleta Group

LOCATION: sec. 26, T. 4 N., R. 101 W.

LCRM This deposit is located in the Skull Creek area.

PROD As of 1971, 19 tons of ore had been mined at a grade of 0.11% U308, producing 42 lbs of U308.

HOST The host is the Jurassic Carmel Formation.

DOI 1971

REF U.S. A.E.C., 1971, Production Records, Colorado.

## Coal Ridge

LOCATION: T. 4 N., R. 101 W.

LCST UNCERTAIN

QUAD Skull Creek 7 1/2' or Lazy Y Point 7 1/2'

HOST The radioactivity occurs in a lignite bed of the Upper Cretaceous Lower Lies Formation of the Mesaverde Group.

MNZ Samples averaging 0.081% U308, with maximums to 0.40% U308 were taken.

DOI 1977

REF Atlantic Richfield Corporation, 1977, Personal Communication.

## Doc Armor Mine

LOCATION: S1/2N1/2 sec. 33, T. 8 N., R. 91 W.

DVEL This was a shallow open pit mine.

PROD As of 1971, 784 tons of ore had been mined at grades of 0.13% U308 and 0.01% V205, producing 2,016 lbs of U308 and 131 lbs of V205.

HOST The deposit lies in the Eocene Wasatch Formation.

MNZ Carnotite - tyuyamunite - type mineralization was recognized.

DOI 1971

REF U.S. A.E.C., 1971, Production Records, Colorado.

## Epsilon Claims No. 3, (56-14, Airborne Anomaly)

LOCATION: sec. 18, T. 7 N., R. 92 W.

LCRM This anomaly is approximately 2,000 ft southeast of Airborne Anomaly 56-13. Directions to the deposit are given as follows: "Beginning at Craig, Colorado, go 12.5 miles west on US Highway 40. Turn right off Highway 40 onto Moffat County Road 15 and go 0.8 miles, turn left and go 1.7 miles. The anomalous area is on top of a rounded ridge 0.7 mile east."

QUAD Lay SE 7 1/2'

MAP CRAIG

DVEL Underground mining was carried out. Two small open pits are located on Epsilon Claim No. 3.

BKG .015 mr/hr

RNG .03 to .10 mr/hr

HOST The host rock is Miocene Browns Park Formation. It is a gray to buff, fine- to medium-grained sandstone and siltstone with locally abundant ilmonite staining, and some CaCO3 cementation.

MNZ Uranium mineralization was found, although it was not megascopically visible. It appears to be associated with the ilmonite staining.

DOI 1955

## Farnsworth Uranium Deposit (Housel Gulch Placer, Pardner, Friendship, Magpie, Sage Hen, Housel Gold Placer Mine, Pal, Grey Hound Leases)

LOCATION: sec. 9, T. 9 N., R. 92 W.  
 LCRM The deposit also extends to sec. 4.  
 QUAD East Timberlake Creek 7 1/2'  
 HOST The host is the Eocene Watsatch Formation.  
 MNZ Uranium, thorium and vanadium mineralization is present, with ilmenite and monazite recognized in black sands on the property.  
 DOI 1975  
 REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. Geol. Survey, 1977, CRIB File.

## Fly Claims (Iles Formation)

LOCATION: NE1/4NW1/4 sec. 17, T. 3 N., R. 101 W.  
 LCRM There are also claims in sec. 7, 8, 16, and 18, all on or near Coal Ridge.  
 QUAD Rangely NE 7 1/2'  
 RNG 2,000 to 5,000 cps  
 HOST The host is a fine-grained sandstone and thinly bedded lignite of the Upper Cretaceous Iles Formation. The mineralization occurs in the lignite near contacts with the sandstone. The lignite becomes barren as the distance from that contact increases.  
 STRC The beds dip 58° to 65°S, and strike N65°W.  
 ALT The sandstone has been bleached.  
 MNZ There is irregular secondary mineralization with visible carnotite or autunite in the sandstones. Assays show values of 0.034% U3O8 in the sandstones and 0.051% U3O8 in the lignite.  
 DOI 1977  
 REF Atlantic Richfield Corp., 1977, Personal Communication. Western Nuclear, Inc., 1977, Personal Communication.

## Gertrude Mine (Gertrude No. 5 and No. 6 Claims)

LOCATION: NW1/4NE1/4 sec. 17, T. 7 N., R. 94 W.  
 LCRM Directions to the deposit are given as follows: "Drive 3.7 miles west of Lay, Colorado on U.S. Hwy 40. Turn right on to a trail, go through a gate, and drive 2.8 miles to a fork in the road. Take the left fork and drive 1.1 miles to the deposit."  
 QUAD Lay 7 1/2'  
 PROD As of 1971, 355,332 tons of ore were mined at a grade of 0.12% U3O8, producing 785,329 lbs of U3O8.  
 BKG .02 mr/hr  
 RNG .05 to 4.5 mr/hr  
 HOST The mine lies in the Miocene Browns Park Formation. The host is a light gray to buff, friable, fine- to medium-grained sandstone. It is more than 700 ft thick at this point, and rests with an angular unconformity on the older sediments. The ore occurs in flat, irregular lenses ranging in depth from 6 to 200 ft.  
 STRC The beds strike N60°E and dip 10°SE. Four faults, showing displacements ranging from 1 to 2 ft, strike N50° - 70°W.  
 MNZ Uranophane and meta-autunite are the important ore minerals in the oxidized zone. Coffinite

was the only mineral identified in the unoxidized zone. Channel samples assayed 0.212% to 0.236% eU3O8 and between 0.212% and 0.543% U3O8.

DOI 1956  
 REF U.S. Geol. Survey, 1977, CRIB File. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1971, Production Records, Colorado. Finch, W. I., 1967, p. 9. U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado.

## Glory Bee

LOCATION: sec. 5, T. 3 N., R. 101 W.  
 LCRM This deposit lies in the Skull Creek district.  
 PROD As of 1971, 17 tons of ore were mined at grades of 0.04% U3O8 and 0.16% Y2O5, producing 15 lbs of U3O8 and 16 lbs of Y2O5.  
 HOST The host is the Jurassic Curtis Formation.  
 MNZ Copper minerals and brown iron oxide minerals were found associated with carbonaceous material and uranium minerals in the radioactive zone.  
 DOI 1971  
 REF U.S. A.E.C., 1971, Production Records, Colorado.

## Golden Grain Claims

LOCATION: sec. 30, T. 8 N., R. 91 W.  
 LCRM Directions to the deposit are given as follows: "From the junction of US Hwy 40 and State Secondary road 355 west of Craig, Colorado, drive north on the main travelled road 8.5 miles to the Butler Ranch. Turn left through the Butler Ranch and follow a winding road through a wheat field 1.5 miles to the Golden Grain Claims. The anomaly is located on Claim No. 2."  
 QUAD Pine Ridge 7 1/2' or Craig NW 7 1/2'  
 BKG .05 mr/hr  
 RNG .08 to 10.0 mr/hr  
 HOST The host is an outlier of the Miocene Browns Park Formation. The anomalous radioactivity occurs in a dark buff to brown, medium-grained, iron-stained, poorly consolidated member of the formation.  
 MNZ Uranium mineralization was recognized. A light green to yellow fluorescent uranium mineral coats sand grains and is disseminated throughout the sandstone.  
 DOI 1955  
 REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado.

## Hazel Whetstone Property

LOCATION: sec. 27, T. 7 N., R. 94 W.  
 LCRM Directions to the deposit are given as follows: "Begin log at junction of Moffat County Road 53 and US Hwy 40, 8.0 miles east of Maybell, Colorado. Go east on U.S. Hwy 40 for 0.6 miles. The property lies in a narrow gulch trending north and south. A bladed road and some mine workings may be seen at the head of the gulch. The gulch lies one-quarter of a mile north of the highway."

# MOFFAT COUNTY

QUAD Lay 7 1/2'  
 BKG .015 mr/hr  
 RNG .03 to .2 mr/hr  
 HOST The host is the Miocene Browns Park Formation. The maximum radioactivity occurs in a six ft bed of blue, fine- to medium-grained quartzite. The rock is intensely iron stained along fracture surfaces.  
 ALT Alteration has taken place along the fractures.  
 MNZ Very thin, irregular stringers of green to yellow uranium minerals were irregularly deposited in the rock. These stringers are found near the contact line between the altered and unaltered portions of the rock.  
 DOI 1954  
 REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado.

## Hex Claims

LOCATION: sec. 22, T. 8 N., R. 98 W.  
 LCRM Directions to the deposit are given as follows: "From Maybell, Colorado go 0.5 mile west on US 40; turn right and go 19.8 miles on State Highway 318 to the west side of the bridge over Sand Wash Creek."  
 QUAD Lone Mountain 15'  
 BKG .02 mr/hr  
 RNG .05-.08 mr/hr  
 HOST The host is the Miocene Browns Park Formation. The anomalous radioactivity occurs in a petrified log (4 ft in diameter and 10 ft long) in a medium-grained sandstone horizon at the base of a conglomerate composed of red sandstone and quartzite boulders and pebbles. The petrified log is less than five ft above a flat-lying green sandstone of an older formation.  
 STRC The conglomerate dips 17°S and was deposited above an angular unconformity. The beds on the lower side of the unconformity are nearly flat lying.  
 MNZ Uranium mineralization was recognized, but no uranium minerals were seen.  
 DOI 1955  
 REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado.

## Hudson Claim Group

LOCATION: sec. 8, T. 7 N., R. 95 W.  
 LCRM Directions to the deposit are given as follows: "Begin log at Victory Hotel in Maybell, Colorado. Go north on Moffat County Road 19 for 3.5 miles; turn right at wrecked car body; go 0.2 miles, turn left on trail to north; go 1.2 miles, turn left at pile of tin cans; go 0.4 miles, take right fork; go 0.1 mile; anomaly lies here."  
 QUAD Maybell 15'  
 BKG .015 mr/hr  
 RNG .05 to .07 mr/hr  
 HOST The host is the Miocene Browns Park Formation. The anomaly occurs in an iron cemented, brown conglomerate. Slightly abnormal radioactivity

was noted in thin, irregular lenses of green to yellow sandstones which underlie the conglomerate bed.

MNZ Uranium mineralization was recognized, but no uranium minerals were visible. Thin, irregular stringers of gypsum and calcite occur through the beds.  
 DOI 1954  
 REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado.

## Humming Bird Claim (B17-100, Airborne Anomaly)

LOCATION: NW1/4SE1/4 sec. 15, T. 7 N., R. 94 W.  
 LCRM The directions to the deposit are given as follows: "Begin log at junction of U.S. Hwy 40 and Moffat County road 53 west of Lay, Colorado. Go west on U.S. Hwy 40 for 0.1 mile, turn right through fence gate; go 0.7 mile, turn left through fence; go 0.5 mile, take right fork through fence; go 1.0 mile, turn right on faint trail along fence; go 0.5 mile to fence corner, turn left along fence for 0.2 mile; anomaly lies one-half mile to the right at the base of Sugar Loaf Mountain."  
 QUAD Lay 7 1/2'  
 BKG .015 mr/hr  
 RNG .025 to .045 mr/hr  
 HOST The host is the Miocene Browns Park Formation. The deposit occurs in a brown to white, fine- to coarse-grained, calcareous, alluvial sand. This alluvium is underlain by a flat-lying white, calcareous, fine- to coarse-grained sandstone.  
 MNZ Uranium mineralization was noted, but no uranium minerals were visible.  
 DOI 1954  
 REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado.

## Iron and Copper Claims

LOCATION: sec. 14, T. 7 N., R. 94 W.  
 LCRM Directions to the property are given as follows: "From the Standard service station in Maybell, Colorado, drive north on a county road 1.6 miles; turn right and go 1.4 miles; turn left and drive 1.0 mile, turn right and go 1.3 mile to a wash, follow the bottom of the wash north 1.6 mile to the discovery area."

### Unnamed No. 14

LOCATION: sec. 14, T. 9 N., R. 96 W.

QUAD Maybell 15'

RMKS Drilling was carried out by the Cleveland Cliffs Iron Company in 1968. The holes were on 3 mile centers. 23 of 125 holes were mineralized, most in the location given above.

DOI 1977

REF Western Nuclear, 1977, Submittal Files.

### Woodpile No. 1

LOCATION: sec. 11, T. 4 N., R. 101 W.

LCST UNCERTAIN

LCRM The deposit also extends to sec. 12. Directions to the deposit are given as follows: "From Vernal, Utah, at intersection of U.S. Hwy 40 and Utah State Hwy 44, drive east on U.S. Hwy 40 for 57.2 miles to Skull Creek, Colorado; turn left at steel gate for 1.7 miles; right 0.2 mile; right 1.4 miles to discovery of Woodpile No. 1."

HOST The deposit lies near the base of the Shinarump Member of the Triassic Chinle Formation. It is a white, conglomeratic, cross-bedded, poorly sorted sandstone containing red and green mudstone galls and partings. There are numerous minor scours along the rim of the outcrop. The mineralized sandstone unit overlain by mudstone is at the base of the Shinarump and probably occupies shallow scours in the Moenkopi Formation. The weakly radioactive pyritized sandstone is less than one ft thick and is exposed for an outcrop thickness of about 5 ft.

STRC The property is located on the east flank of the Red Wash anticline. The dip is about 8°E.

MNZ Weak mineralization is apparently associated with pyrite masses and nodules. Pyrite is in places interstitial, and in places completely replaces the sand grains. Uranium minerals are not megascopically visible. A grab sample assay showed 0.01% eU308, 0.04% V205 and 2.6% CaCO3.

DOI 1955

REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Moffat County, Colorado.

## MONTEZUMA COUNTY

Production in the county to 1971 was 455 tons of ore mined that contained 1,449 lb of  $U_3O_8$ , and 14,343 lb of  $V_2O_5$ . There is excellent potential for more reserves to be found in the county.

Montezuma County is situated in the Four Corners region of southwestern Colorado. It is mesa country, with the mesas capped primarily by Upper Cretaceous rocks, including the Dakota Sandstone and the Mancos Shale. Older sedimentary formations are exposed locally in the many canyon walls. The Tertiary La Plata Mountains of the San Juan Uplift straddle the eastern border, and the Ute Mountains, also Tertiary in age, dominate the west-central part of the county. Older sedimentary strata are exposed around the flanks of the La Plata Mountains in the northeast.

Two types of radioactive deposits are found in the county. The most important of the two is the Colorado Plateau-type tabular deposit, located predominantly in the Jurassic Morrison Formation, but also found occasionally in the Entrada Sandstone or in the Navajo Sandstone. The Morrison Formation in this area is an interbedded sandstone and mudstone unit. The sandstones are generally white, light gray, yellow, or pale brown, and the mudstones are variegated red and green. In the Salt Wash Member of the Morrison Formation, where most deposits lie, the mudstones are predominantly red. In Montezuma County these deposits are concentrated around McElmo Dome on the northwest flanks of the Ute Mountains. The Roberta Jean Mine, located on the flanks of the McElmo Dome, is the largest uranium mine of this type in the county.

Heavy-mineral concentrations in the Point Lookout Sandstone Member of the Mesaverde Group form the second type of radioactive deposit. These deposits, discovered by airborne reconnaissance surveys during the 1950's, are found along the outer northwest edge of the San Juan Basin.

The majority of the ore shipped from the county was from the Roberta Jean Mine. All of the reported production in the county has been from the Morrison Formation, and most of that was from the Salt Wash Member.

Montezuma County was heavily prospected during the uranium boom of the early 1950's, and any large, easily found deposits should have been discovered at that time. Several formations and areas, however, have further potential. Because of the known prospects and minor production in the area, the Morrison Formation along the flanks of McElmo Dome probably offers the best potential for uranium resources. The Morrison Formation is known to be a favorable host rock for this general area of the Colorado Plateau, and the McElmo Dome appears to have acted as a structural trap for uranium and other minerals. In addition to the occurrences listed in this report, small, scattered anomalies, also reported in the Morrison Formation, are found in Cross Canyon south of Dove Creek. Channel sandstones within the Upper Cretaceous Fruitland Formation in the San Juan Basin are also known to host uranium. The Fruitland could be a potential producer where it extends into Montezuma County on the southeast. At least one occurrence in the county is found within the Jurassic Entrada Sandstone. This occurrence contains some micaceous minerals and a relatively high ratio of vanadium to uranium. Large uranium-vanadium deposits in the Entrada Sandstone have been mined north of Montezuma County at the Graysill Mine in San Juan County and at Placerville, San Miguel County. Those within the county could be genetically similar to these roscoelite types. The final area of interest lies on the northwest edge of the San Juan Basin, where ancient heavy-mineral placers are found in the black sands of the Point Lookout Sandstone (Mesaverde Group) and Picture Cliffs Sandstone. These placers probably do not have much economic potential for uranium, but may be of some importance as rare-earth or titanium concentration.

 REF W. L. Chenoweth, 1978, Personal Communication. U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Montezuma County, Colorado. Chenoweth, W. L., and Stehle, F. T., 1957.

## 31, Airborne Anomaly

LOCATION: SE1/4NW1/4 sec. 23, T. 32 N., R. 17 W.  
 LCST UNSURVEYED  
 LCRM "Turn east from U.S. Highway 666 onto dirt road 11.5 miles north of Shiprock, N.M. Drive along well-travelled road to top of Palmer Mesa. Turn left at a group of hogans 8.4 miles from the junction with Route 666 and proceed northeast 2.4 miles to the Ute Res. fence; continue for 0.4 mile, then turn west and drive for 2 miles. Anomaly is a long drainage to left of the road." This anomaly lies in the northwestern San Juan Basin.  
 QUAD Tanner Mesa 7 1/2'  
 MAP CORTEZ  
 HOST The anomaly is located in the upper part of the Point Lookout Sandstone of the Upper Cretaceous Mesaverde Group. The radioactivity occurs in a dark brown to dark yellowish-brown, very fine-grained blocky sandstone that is well-cemented with limonite. This limonite zone occurs in a light gray, massive, cross-bedded sandstone. Some blotches of reddish-brown friable sandstone with hematite and jarosite occur at the contact with the massive and mineralized sandstone.  
 STRC The deposit is located on the northeast flank of the North Chimney Rock dome.  
 MNZ Mineralization is not megascopically visible but is due to detrital heavy minerals such as uraniferous zircon or monazite. The mineralized sandstone occurs as a brown colored zone which is exposed for 800 ft along the outcrop for a width of 50 to 100 ft and a thickness of 2-3 ft. Chip channel samples had values between 0.01 and 0.06%  
 RMKS Anomaly No. 30 is 1/4 mile to the northwest. Anomalies numbered 25, 26, and 27 are across the canyon about one mile to the north.  
 DOI 1955  
 REF W. L. Chenoweth, 1978, Personal Communication. U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Montezuma County, Colorado. Chenoweth, W. L., and Stehle, F. T., 1957.

## 38, Airborne Anomaly

LOCATION: E1/2NW1/4 sec. 12, T. 33 N., R. 17 W.  
 LCST UNSURVEYED  
 LCRM "Turn east from U.S. Highway 666 at a point 9.6 miles north of Mancos River Trading Post. Drive 2.7 miles past two reservoirs to the end of the road. Climb the mesa via the horse trail at the right. The Anomaly is about 2 miles across the top of the mesa from the top of the trail." This anomaly lies in the northwestern San Juan Basin.

# MONTEZUMA COUNTY

QUAD Towaoc 7 1/2'  
 MAP CORTEZ  
 HOST The host rock is the Upper Cretaceous Mesaverde Group. Mineralization occurs in the upper massive member of the Point Lookout Sandstone at or near the contact with the overlying Menefee Formation. The radioactivity is located in a dark, yellowish-brown, dark brown, to dark reddish-brown, very fine-grained, well-cemented, blocky sandstone. The mineralized rock is a distinctive brown color which is diagnostic of anomalies in this area. The mineralized zone is exposed for about 400 ft along the outcrop for a width of 75 ft and a thickness of 2-3 ft.

MNZ Mineralization is not megascopically visible, but probably occurs in detrital heavy minerals such as uraniferous zircon and monazite.

RMKS Anomalies 38, 39, and 41 to 44 are all believed to represent the same "shoestring" sand, now separated by canyons and cover.

 DVEL Some underground work had been carried out, but there is no record of any uranium production.  
 BKG .004 mr/hr  
 RNG .006 to .02 mr/hr  
 HOST The host is a white, medium-grained sandstone that is reported as either Jurassic upper Navajo or lower Carmel. It outcrops in varying degrees for a distance of one mile.  
 MNZ Grab samples show weak to moderate radioactivity. The radioactivity originates from a brownish-red limonite gossan. Veins of pyrolusite, crusts of barite, and stains of copper are also associated with the uranium mineralization.  
 DOI 1951  
 REF W. L. Chenoweth, 1978, Personal Communication. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Montezuma County, Colorado. Metzger, O. H., 1944.

### Coffin's Prospect

LOCATION: sec. 34, T. 36 N., R. 18 W.  
 LCRM The prospect lies a few feet north of Colorado Highway 32 on the John Meadows Ranch.  
 QUAD Moqui SE 7 1/2'  
 MAP CORTEZ  
 DVEL A pit was opened in 1913, but no ore was shipped from this prospect. The pit is now filled with alluvium.  
 HOST The deposit lies in the Entrada Sandstone.  
 STRC The prospect lies near the Ute Mountains, and many fractures and faults cross the area. These fractures do not seem to have controlled mineralization.  
 MNZ The mineralized zone is about 6 inches thick and is exposed along an outcrop that is 130 ft by 40 ft wide. There are uranium-vanadium minerals and traces of malachite present, concentrated along bedding planes. Within the mineralized zone, a dark gray, 1-inch seam is higher grade than the rest of the zone. The dark gray mineral is believed to be a vanadium mica. Samples taken in 1921 assayed more than 1.0% V2O5 and 0.09% U3O8. Samples taken in the early 1960's assayed .004 to .008% eU3O8 and .52 to .93% V2O5.

## MONTROSE COUNTY

Montrose County lies within the Uravan mineral belt and is the most important producing county in the belt and the state. Production in the county from January 1, 1948 to January 1, 1978 was 7,369,000 tons of ore mined at a grade of 0.25 percent  $U_3O_8$  producing 36,428,000 lb of  $U_3O_8$ . Of the ore mined, 7,321,000 tons were processed for vanadium, producing 187,104,000 lb of  $V_2O_5$  at a grade of 1.28 percent of  $V_2O_5$ .

The county is situated on the western slope of Colorado, and it lies within typical Colorado Plateau terrane. The county is covered by Cretaceous, Jurassic, and Tertiary sediments. These rocks are exposed on mesas and plateaus or in valleys along the San Miguel and Dolores Rivers. Salt anticlines in Paradox Valley and the Sinbad Valley expose the Pennsylvanian Paradox

Formation, which consists of salt, gypsum, and anhydrite in a thick evaporite sequence. Some Precambrian rocks are exposed on the Uncompahgre Plateau in the northeastern part of the county.

The Brushy Basin Member of the Morrison Formation is the most important host of uranium deposits in the county. The ore is contained within tabular or roll-type bodies in stream-channel sands. The Morrison contains large amounts of organic matter that is regarded as a favorable criterion for ore.

The county will remain a producer of ore for years to come. Much has been written about the county and the belt in particular. These references can be found in the cross-index of the bibliography and should be consulted for more information.

## MORGAN COUNTY

There are no recorded occurrences of uranium in the county. The potential for resources to be found in the county is poor.

The county is largely covered by Quaternary eolian deposits, and in some places Cretaceous Pierre Shale

is exposed. Recent gravels and alluvium fill the river valley of the South Platte River.

None of the rocks that outcrop in the county are considered to be favorable host rocks for uranium. This makes the potential for resources of uranium to be found in the county very small.

## OTERO COUNTY

No uranium occurrences have been found in the county to date, and the potential is fairly low for discovering any. The surrounding counties have very minor occurrences but none that would indicate any extension into Otero County.

Otero County lies in the southeastern part of the state in sedimentary terrane, primarily of Late Cretaceous age. The Niobrara Formation is exposed over much of the county, with Dakota Sandstone, and Benton Shale also covering large areas. A few exposures of the Lower Cretaceous Purgatoire Formation and the

Jurassic Morrison Formation are found, with alluvium covering much of the Arkansas River Valley floor.

Uranium deposits in the Lower Cretaceous Dakota Sandstone and in the Jurassic Morrison Formation have proved economic in the past in other parts of the state, and it is conceivable that resources could also exist in these units within Otero County. The Dockum Group (Upper Triassic) has shown limited potential in certain southeastern areas of the state, and exploration drilling could possibly discover some mineralization in that formation at depth.

## OURAY COUNTY

No production of uranium from Ouray County has been reported. The potential for known occurrences to become reserves is small.

The county lies on the northern edge of the San Juan Uplift and is partially covered by the Tertiary volcanic rocks associated with the uplift. The northern half of the county is largely covered by Cretaceous rocks, including the Mancos Shale and the Dakota Sandstone. These sediments dip away from the uplift and quickly become flat-lying in the northern part of the county.

Almost all of the occurrences in Ouray County are associated with some type of hydrothermal activity. They are associated with veins whose primary values are for silver, gold, lead, and zinc. None of the occurrences have potential for developable uranium reserves. The one exception is a group of occurrences in the Uncompaghe slates and quartzites near Bear Creek Falls. These occurrences are reported to contain only uranium as the primary metal, with associated minor pyrite. Although these rocks show some potential for some developable reserves, the area of outcrop of the Uncompaghe is limited in the county.

## PARK COUNTY

Production from Park County has been small. Records show that by 1971, 1,579 tons of ore had been mined, producing 5,532 lb of  $U_3O_8$ . Excellent potential exists for uranium reserves to be found within the county.

The geology of the county is quite complex. Rocks of many ages and types are juxtaposed by Tertiary intrusions and a series of northwest-southeast-trending faults and fault zones.

A large part of the county lies within South Park, an Intermontane basin ranging from 9,000 to 10,000 feet in elevation. Mesozoic and Upper Paleozoic rocks crop out in the basin.

The Park Range bounds the county on the west, and mountains of the Front Range bound it on the east. Precambrian rocks comprise most of the Front Range, and lower Paleozoic rocks and Tertiary intrusions form the Park Range. Uranium occurrences in the county are found in many of these rock types and structures.

The most important occurrences in the county include Garo Deposit-Shirley May Mine, Gem Dandy, Lucky Jim, and Tedco and Mac George. These mines account for over 90 percent of the uranium production within the county. The Tedco-Mac George and Gem Dandy prospects are located within a mile of each other near Kenosha Pass. The uranium in these prospects occurs as pods and lenses of autunite and uraninite in northwest-trending shear zones within Precambrian granite and biotite gneiss.

The Shirley May Mine near Garo has been explored for various metals since 1900 and was operated as early as 1919 for radium ore. In 1952 the mine was evaluated by the U.S. Geological Survey for uranium and vanadium resources. Uranium, vanadium, and copper are found in faulted sandstone blocks of the Permo-Pennsylvanian Minturn Formation at the deposit. The ore bodies are small, and reserve potential at the site appears to be limited. However, this type of occurrence is common in the Minturn Formation from the area of Vail Pass south to the southern Sangre de Cristo Range, and other prospects of this type may have better uranium potential.

The Lucky Jim Mine is approximately 14 miles north of the community of Hartsel. Forty-seven percent of all production from the county came from this mine. The uranium occurs in lake beds of the Tertiary Antero Formation east of the Elkhorn Thrust Fault. The fault separates the Antero Formation from Precambrian granitic rocks. Autunite, found along fractures and bedding planes, is reported to be the primary ore mineral.

Tertiary lacustrine sediments such as the Antero Formation and the Florissant lake beds have high potential for uranium reserves. Shear zones in Precambrian also have very good reserve potential. These are the two most extensively explored geologic environments in the county because they have been the hosts for a large amount of uranium produced. Uranium occurs in other geologic environments, and the possibility of uranium resources at these sites or in similar environments should not be discounted.

## PHILLIPS COUNTY

No uranium occurrences are reported in Phillips County. The county is underlain by flat-lying Tertiary Ogallala Formation with some minor Quaternary sediments. Potential for uranium resources in the county are small. Sandstone-type uranium occurrences in the Ogallala Formation are the most likely to be found.

## PITKIN COUNTY

The only recorded uranium production from the county as of 1971 was from the Frying Pan Claims, which produced 62 tons at an average grade of 0.14 percent  $U_3O_8$ . Potential for more reserves to be found is very limited.

The seat of Pitkin County is the city of Aspen--one of the oldest and richest silver mining camps in Colorado. It is located in west-central Colorado and includes some of the state's most rugged mountains. The Elk Mountains and the Sawatch Range dominate with mountain peaks towering over 14,000 feet. Precambrian rocks are found in the Sawatch Range, and Pennsylvanian-Permian formations are dramatically exposed in the Elk Mountains. The southern extension of the Grand Hogback Monocline crosses the western part of the county from north to south. Roughly paralleling the Grand Hogback but cutting the center of the county is the Castle Creek Fault, which forms the eastern border of the Elk Mountains. Trending northwest to southeast between the Grand Hogback and Castle Creek Fault is the Roaring Fork Syncline. The Sawatch Range Anticline and the Homestake Shear Zone lie in the northeastern corner of the county, and the Grizzly Caldera is directly south of them on the southern border. Precambrian rocks in the Grizzly Mountains are overlain by Tertiary intrusives and extrusives. Sedimentary formations ranging in age from Cambrian to Late Cretaceous cover much of the rest of the county.

The Frying Pan Claims, because of their production, are the most important known uranium occurrences in the county. They are similar in nature to the other uranium occurrences found in the county, all of which lie in fault breccias that host the silver and lead ores found in the old mines near Aspen. Most of these fault breccias cut the Pennsylvanian-Permian Weber Shale and the Mississippian Leadville Limestone, but some are found in the Precambrian granites as well. In all cases the Precambrian rocks and Tertiary intrusives are intimately associated with the mineralization.

Based on known occurrences, the Aspen district appears most favorable for additional uranium occurrences. However, the potential for reserves to be developed is small. Uranium mineralization found in the Aspen district is associated with silver and lead ores from the old mines. If any of the mines were reopened for silver and lead, the uranium could possibly be extracted as a by-product. The other potential area in the county is the Grizzly Caldera in the southeastern part of the county. There, Tertiary intrusives are exposed within the caldera, and related extrusives lie around the borders. This caldera could be the host for volcanogenic deposits such as are found in other parts of the world.

 REF U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Pitkin County, Colorado.

## PROWERS COUNTY

Neither production nor occurrences are reported from the county. The potential for any uranium resources to be found is very limited.

Prowers County lies on the southern flank of the Las Animas Arch in the southeastern corner of Colorado. The terrane is almost entirely sedimentary, with nearly equal proportions of Cretaceous Niobrara Formation, Benton Group, and Dakota Sandstone, and Miocene-Pliocene Ogallala Formation covering the county. A few small early Tertiary intrusives are found in the extreme southern part of the county along Two Butte Creek, with older formations locally exposed by the uplift associated with the intrusions.

No uranium occurrences are known within the county. In other areas of the state the Dakota Sandstone and the Jurassic Morrison Formation are favorable hosts for uranium deposits. The Dockum Group also shows interesting anomalies in other parts of the state, and exploration drilling could possibly detect some mineralization at depth. Water sampling done by the U.S. Geological Survey has shown higher than average readings of uranium from waters draining the Ogallala Formation north of the Arkansas River. Some exposures of Ogallala are found in the extreme northeastern section of the county, and these also have some potential.

## PUEBLO COUNTY

Production appears to have been limited to one deposit, the George Avery Ranch Mine, which shipped 10,553 tons of ore at an average grade of 0.15 percent  $U_3O_8$ , producing 32,213 lb of  $U_3O_8$  by 1971. Most of this production came in the late 1950's; no recent work is known to have taken place. Potential for more reserves to be found in the county is small.

Pueblo County, located in the south-central part of the state, is dominantly covered with sedimentary rocks ranging in age from Cambrian to Quaternary. A small portion of southwestern Pueblo County contains Precambrian crystalline rocks of the Wet Mountains. In general, the youngest rocks lie in the northeastern quarter of the county, and become progressively older toward the southwest.

The George Avery Ranch contains what are probably the most important occurrences in the county. They are tabular deposits within the Cretaceous Dakota Sandstone and are associated with carbonaceous material. The deposits lie on the eastern flank of the Turkey Creek Anticline in the northwestern corner of the county and are related to occurrences nearby in El Paso County. This and two other occurrences lie within the Fort Carson military reservation, and access to them is limited.

Additional small, scattered ore bodies will probably be found in the Dakota Sandstone within the county. Known isolated occurrences are associated with fossils in the Jurassic Morrison Formation. Further exploration in both formations could develop further reserves in them; however, the potential is limited for the county.

PROD By 1971, 10,553 tons of ore had been mined at an average grade of 0.15% U308, producing 32,213 lbs of U308.

BKG .02 mr/hr

RNG 1.0 to 5.0 mr/hr

HOST The host is Cretaceous Dakota Sandstone(?); gray to buff, fine-grained sandstone with carbonaceous fragments.

STRC A vertical fracture 0.4 ft wide is present but is not radiometrically anomalous.

MNZ There is a yellow coating (carnotite?) on the sandstone, in small solution cavities, and as minor fracture filling. Some uraninite is also present. Chip assays covered the range of 0.03-0.23% U308, with one assaying at .063% U308, a 0.4 ft channel sample had a value of 0.103% U308.

## RIO BLANCO COUNTY

As of 1971 production from the county totaled 36,637 tons mined which produced 223,679 lb of  $U_3O_8$ , and 832,933 lb  $V_2O_5$ . The county is one of the major producers in the state, and potential for more reserves to be found is excellent. Small-scale mining will continue in the Coal Creek district as long as the price remains at its present value.

Rio Blanco County is situated in the northwestern part of the state. Most of the county lies within the Piceance Creek Basin, an elongate, northwest-trending structure. The north-trending Grand Hogback Monocline forms the boundary between Cretaceous and Tertiary sediments in the Piceance Creek Basin and Paleozoic sediments and Tertiary volcanics in the White River Plateau. At the north end of the Grand Hogback, about 15 miles northeast of Meeker, lies the Coal Creek Anticline, a small uranium district. Uranium mineralization is found where the Morrison Formation is exposed around the nose of the anticline. The ore is of the carnotite-type and concentrated in the Salt Wash Member of the Morrison Formation. This belt of mineralization is less than a mile wide and six miles long.

Most of the deposits in the county are small, commonly less than 500 tons, and were mined by small strip operations and underground methods.

The largest producing mine in the county is in the Midnight Group of claims, where over 12,000 tons of ore were mined and shipped. This and all other large producers--Burrell 1, 2, 3, and the Burrell 5, the Butterfly Group, and the Shylo Group are located in the Coal Creek district. The Burrell Mines and the Butterfly Group are separate mines all lying within the same claim group. The Salt Wash Member of the Morrison Formation was the host for these deposits and for most other mines in the county.

Additional small occurrences or deposits will probably be found in the Salt Wash Member of the Morrison Formation near the Coal Creek Anticline. Small occurrences have been reported on the White River Plateau where older sedimentary rocks are exposed along the Grand Hogback. Any study of potential within the county should include those rocks of the hogback, with emphasis on the Triassic Chinle Formation and the undivided Pennsylvanian-Permian section. They all host uranium deposits either in this county or in nearby counties. Of the younger rocks to the east, the Lower Cretaceous Dakota Sandstone, the Upper Cretaceous Iles Formation, and the Tertiary Wasatch Formation may be potential hosts as these, too, are known to contain uranium deposits in this or neighboring counties.

## RIO GRANDE COUNTY

There is no production of uranium from this county, nor are there any reported occurrences.

The county has two geologic terranes. One is the San Luis Valley Graben, which is a downdropped block filled with thick Quaternary sediments. The other terrane, in the western part of the county, is dominated by Tertiary volcanic rocks.

Although no uranium occurrences are reported, some potential exists for uranium resources to be found within the county. In the volcanic terrain is the possibility of uranium mineralization emplaced during several periods of volcanogenic development. The area around the edges of the caldera near Summitville has good potential for this type of occurrence. The sediments of the San Luis Valley have small potential for sandstone-type of occurrences in the subsurface.

## ROUTT COUNTY

No production of uranium has been reported from Routt County to date. Geologically, the county is dominated by relative flat-lying Cretaceous and Tertiary sediments. The exception is the Park Range on the eastern edge of the county where the uplift has exposed Precambrian rocks.

The potential of the county to contain uranium reserves appears to be limited. Many of the rock types that crop out in the county are not considered favorable hosts for uranium mineralization. Examples are the extensive outcrops of the Mancos and Lance

Shales in the western part of the county, and large areas of gneiss in the Park Range on the eastern area of the county.

The Browns Park Formation and Iles Formation have the potential to contain important sandstone-type occurrences similar to those found near Maybell in Moffat County. Granitic rocks, such as the Sherman and Mount Ethel Granites that are exposed in the Park Range could contain uranium occurrences, although not much is known about uranium in these rocks.

## SAGUACHE COUNTY

Uranium production from the county as of 1971 totaled 596,494 tons of ore at an average grade of 0.22 percent  $U_3O_8$ . Development is beginning on a major mine with excellent possibility of more reserves being found in the county.

Igneous rocks of the Miocene Potosi Volcanic Series cover much of Saguache County, located in south-central Colorado. Paleozoic sediments and Precambrian rocks are found along the Sangre de Cristo Range on the eastern edge of the county. These two areas are separated by the valley of the San Luis Graben, which is filled with thousands of feet of recent sediments. Paleozoic and younger rocks crop out in scattered locations around the county. In the Sargents-Marshall Pass-Bonanza area is an extensive field of late Tertiary volcanic flows, known as the Bonanza volcanic field.

Most of the production in the county came from mines in the Cochetopa district and in the Marshall Pass area. No production is currently taking place in these areas, but reserves are large, and at least one major mine, the Pitch, will begin operations soon.

Three mines produced 99 percent of the ore mined in the county--the Los Ochos Mine, the Pitch Mine, and the T-2 Mine. The Los Ochos Group and the T-2 Mine lie on the Los Ochos Fault in the Cochetopa district. Here the mineralization occurs where the Los Ochos Fault brecciates the Morrison Formation, the Dakota Sandstone, and the Mancos Shale, which all overlie Precambrian rocks. Morrison Formation sandstones appear to be the most favorable host, but the Dakota Sandstone should not be overlooked.

The Pitch Mine is the important past producer in the Marshall Pass district. The mine has been inactive for many years, but is currently being readied for strip-mining operations. The uranium at the Pitch Mine occurs in the Pennsylvanian Belden Formation. The Pitch Mine and all other occurrences in this area lie on or near the Chester Fault, which displaces Precambrian rocks against remnants of Paleozoic rocks. Although the Belden Formation is mineralized at the Pitch Mine, nearly any of the Paleozoic formations can act as a host. Some of the occurrences, such as the Little Indian No. 36, are found in Harding Quartzite, while others are found in the Leadville Limestone or in the Chaffee Formation.

Saguache County shows excellent potential for the discovery of relatively large ore bodies. The known deposits in this county primarily lie in the Cochetopa district, the Marshall Pass area, and in the Kerber Creek district. The Kerber Creek area's geology is nearly identical to that of the Marshall Pass area. These are the areas with the major potential in the county. In the Cochetopa district, emphasis should be placed on locations where major faults have brecciated the Dakota Sandstone and the Morrison Formation. Mineralization in both the Marshall Pass area and in the Kerber Creek district is found where such structures as the Chester Fault intersect remnants of the Paleozoic section. Similar stratigraphic and structural conditions in Saguache and adjacent counties could yield similar types of deposits.

## Bob Cat

LOCATION: sec. 26, T. 44 N., R. 11 E.

DVEL Discovered in 1953, working consists of open cuts and pits.  
PROD A total of 46 tons of 0.14% U3O8 and 0.08% V2O5 were mined in 1953-1954, producing 131 lbs of U3O8 and 78 lbs of V2O5.  
HOST The host is a zone pegmatite in a Precambrian granite. This pegmatite is one of a series of dikes that cut Precambrian schist, gneiss, and granite in a northwest trending belt 3 miles wide and 25 miles long.  
STRC Near vertical and strikes northwest.  
MNZ Uranium, thorium, and rare earth minerals.  
DOI 1971  
REF R. C. Malan, 1978, Personal Communication. U.S. A.E.C., 1971, Production Records, Colorado.

## Bonita Nos. 1 & 2 Claims (Bonita Claim, Bonita Group)

LOCATION: sec. 23, T. 48 N., R. 7 E.

LCST UNSURVEYED  
LCRM The mine is adjacent to the road. It also extends to sec. 14.  
QUAD Bonanza 15'  
MAP MONTROSE  
DVEL Drifting on the mineralized structure began

In the fall of 1954. Workings as of November 1, 1955 consisted of 375 ft of underground work.

PROD In 1955-1958, a total of 163 tons had been mined at a grade of 0.144% U3O8, producing 472 lbs of U3O8 and 5 lbs of V2O5.  
BKG .08 to .10 mr/hr  
RNG .2 to 1.0 mr/hr  
HOST The host is a carbonaceous regolith of possible Eocene age which rests on Precambrian granite and is overlain by Miocene Potosi Volcanic Series.  
STRC A major fault, which branches out to several faults and steepens where it branches, appears to control the mineralization.  
ALT Heavy wallrock alteration to sericite and kaolinite is present. Heavy hematite alteration exists in the faults.  
MNZ The mineralization appears at one point as minor visible autunite (?) and non-visible minerals in the rhyolitic footwall of the fault. Where the fault branches into vertical trends the mineralization is not megascopically visible, but is associated with the heavy hematite alteration in the faults. Radiometric assays range from 0.008 to 0.35% U3O8, and chemical assays are between 0.026 and 0.526% U3O8. The majority of ore comes from an eight in. seam of black, carbonaceous material which dips 25 ft to the west. The seam occurs between Precambrian granite below and a Tertiary trachyte porphyry above. The primary mineralization is probably of the uraninite - coffinite type with minor pyrite.

DOI 1955  
REF R. C. Malan, 1978, Personal Communication. U.S. Geol. Survey, 1977, CRIB File. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1971, Production Records, Colorado. U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Saguache County, Colorado. Malan, R. C., 1959.

 QUAD Razor Creek Dome 7 1/2'  
 MAP MONTROSE  
 DYEL Numerous claims and prospects were located in 1954. One property had over 355 ft of underground workings, while the owner of the Los Ocho Group developed over 2,500 ft of drifting and did 6,200 ft of core drilling. Drilling has resulted in the discovery of at least two significant ore bodies.

PROD Prior to 1971, 448,685 tons of ore at a grade of 0.14% U3O8 had been mined, producing 1,253,513 lbs of U3O8.

BKG .04 mr/hr

RNG .05 - .5 mr/hr

HOST The deposits occur along a fault where Precambrian granite and schists have been faulted against Jurassic Morrison Formation (Brushy Basin Member). One ore body is in the altered Precambrian schists, while another is in a brecciated, silicified mudstone of the Brushy Basin Member. Most of the ore was mined from sandstone and shale of the Morrison Formation. Mineralization has been found for about a mile along the fault, with most of the ore being in the fault breccia or immediately adjacent rocks. Some ore bodies did extend to as much as 200 ft from the fault into the Morrison Formation.

STRC The Los Ochos Fault is the dominant structure in the area; it is about 3 1/2 miles long. All of the ore deposits are closely related to it spatially. Veins cut the Precambrian rocks. They are one to two ft in width, and were originally mined for gold.

ALT Alteration is reported to be intense in the area of the deposits. The Precambrian rocks are kaolinized, chloritized, and sericitized. The sediments are highly silicified.

MNZ The veins are bound by clay minerals. Autunite is found coating fractures with abundant hematite and ilmenite staining. The radioactive minerals primarily occur in the broken and cemented breccia and include uraninite, autunite, uranophane, torbernite, johannite, uranopilite, and zippelite. Uranium was the principal ore mineral. The gangue minerals were chalcadony, barite, clay minerals, marcasite, and quartz. The uraninite occurred in veinlets of marcasite and clay minerals.

 QUAD Sawtooth Mountain 7 1/2'  
 MAP MONTROSE  
 DVEL Four discovery trenches were dug.  
 BKG .015 - .025 mr/hr  
 RNG .15 mr/hr  
 HOST The rocks in the area consist of Precambrian granite gneiss and the Salt Wash Member of the Jurassic Morrison Formation. The anomalous radioactivity occurs in the Precambrian rocks.  
 STRC A nearly vertical shear zone, striking S55°E, trends through exposures of Precambrian granite gneiss and Jurassic Morrison Formation.  
 MNZ Radioactivity is associated with the intensely sheared, hematite stained Precambrian rocks. A minor amount of disseminated fluorite is present in the sandstone. No visible uranium mineral was noted.  
 DOI 1955  
 REF U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Saguache County, Colorado. Cross, Whitman, and Larsen, E. S., 1935, U.S. Geol. Survey Bull. 843, 138 p.

### Marshall Pass Group Nos. 1-58

LOCATION: sec. 27, T. 48 N., R. 6 E.  
 LCST UNSURVEYED  
 QUAD Pahlone Peak 7 1/2'  
 MAP MONTROSE  
 DVEL The prospect consists of a small pit 10 ft x 10 ft x 6 ft. Two to three tons of ore were stockpiled.  
 PROD In 1956, 18 tons of ore were mined at a grade of 1.06% U3O8 and 0.06% V2O5, producing 380 lbs of U3O8 and 22 lbs of V2O5 from the Marshall Pass No. 5 Claim.  
 BKG .07 mr/hr  
 RNG 20.0 + mr/hr  
 HOST The prospect is in a coarse-grained Precambrian granite that has intruded biotite and muscovite schist. Limestones and quartzites and the Pennsylvanian Belden Shale are all associated with the area. Ore production came from a regolith developed on the Precambrian rocks.  
 STRC The Chester Fault has thrown younger sediments against Precambrian igneous and metamorphic rocks. The mineralization is intimately related to the faulting as at the Pitch Mine northwest of this occurrence. Other north-trending faults occur in this area.  
 MNZ Two samples sent in by the owners assayed 21.40 and 30.0+ % U3O8. The uranium mineral is pitchblende with minor amounts of uranophane (?) and gummite. A minor amount of galena was present in the pitchblende.  
 RMKS This is in the area of the Pitch Mine.  
 DOI 1956  
 REF U.S. Geol. Survey, 1977, CRIB File. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1971, Production Records, Colorado. U.S.

 DVEL Several development cuts and pits were made.  
 PROD In 1954, six tons of 0.20% U3O8 ore were mined, yielding 24 lbs of U3O8.

# SAGUACHE COUNTY

BKG .04 mr/hr  
 RNG .4 to 4.0 + mr/hr  
 HOST Precambrian hornblende gneiss and granite gneiss cut by a zoned pegmatite dike which contains the mineralization. This is one of a series of these dikes which cut Precambrian rocks in a belt 3 miles wide and 25 miles long.  
 MNZ The radioactive mineral is black, heavy, and appears massive. It was described as a "euxenite-type" ore. One sample assayed 0.366% eU308, 0.271% U308 with 0.68% Nb and 0.5% Ta. Other samples assayed ranged in value from 0.015 to 0.032% eU, 0.006 to 0.20% U, 0.031% Th, with minor radium. Minerals are xenotime, monazite, samarskite, garnet and cyrtolite.  
 DOI 1953  
 REF Malan, R. C., 1978, Personal Communication. U.S. Bur. of Mines, 1977, (Unpubl.). U.S. A.E.C., 1971, Production Records, Colorado. U.S. A.E.C., 1966, Preliminary Reconnaissance Reports, Saguache County, Colorado.

## Old Rawley Mine

LOCATION: SW1/4 sec. 18, T. 47 N., R. 8 E.  
 HOST The host is a quartz barite vein in Tertiary volcanics.  
 STRC Veins form along fault fissures or along subsidiary tension fissures in walls of large faults.  
 MNZ 0.25% U. Uranium identified as sooty pitchblende and uraninite.  
 RMKS Pitchblende was also found in the drainage tunnel of the mine. Also in the Whale Mine just south of the Rawley.  
 DOI 1977  
 REF Pierson, C. T.; and others, 1958.

## Pitch Mine (Erie No. 28)

LOCATION: NE1/4NE1/4 sec. 21, T. 48 N., R. 6 E.  
 LCRM The deposit also extends to the NW1/4NW1/4 sec. 22, T. 48 N., R. 6 E.  
 QUAD Pahlone Peak 7 1/2  
 MAP MONTROSE  
 DYEL The mine was first established as an underground mine in the 1950's. Later work has been done on the surface. Homestake Mining Company is in the process of developing an open pit mine on property as of 1977.  
 PROD 104,520 tons were mined prior to 1971 at a grade of 0.58% U308, producing 1,206,112 lbs of U308. In a paper given at the American Institute of Mining Engineers Meeting, Denver 1978, reserves were reported as 2.1 million tons of ore at a grade of 0.17% U308. This would be equivalent to 1.74 million lbs of U308. The pit will be approximately 5,000 ft long by 400 ft deep. It is to be elongated along the Chester Fault with the fault being the axis of the pit.  
 HOST The deposit occurs in the Pennsylvanian Belden shale and limestones where they have been faulted into contact with Precambrian rocks.  
 STRC The Chester Thrust Fault controlled ore deposition in the vein.

ALT Rocks are altered near the fault. Swelling ground necessitated the use of arched steel sets in areas of highly altered Precambrian rocks.  
 MNZ Uraninite, pitchblende, uranophane, and pyrite are found at the mine.  
 REF Ward, J. M., 1978, AIME Conference, Denver. U.S. Geol. Survey, 1977, CRIB File. U.S. Bur. of Mines, 1977, (Unpubl.). Mining Journal, August 1976. U.S. A.E.C., 1971, Production Records, Colorado. U.S. A.E.C., 1959. Malan, R. C., and Ranspot, H. W., 1959. Ranspot, H. W., 1957.

## Rainbow's End

LOCATION: S1/2NE1/4 sec. 33, T. 46 N., R. 9 E.  
 QUAD Villa Grove 7 1/2  
 MAP PUEBLO  
 DYEL The property has no history of production. Workings consist of a few small pits 1-2 ft deep.  
 BKG .02 - .09 mr/hr  
 RNG .18 mr/hr  
 HOST The host rock is Ordovician Harding Quartzite. The Harding Quartzite strikes N60°E and dips N22°W.  
 MNZ The mineralized zone is confined to a 4.5 ft thick carbonaceous bed within the Upper Harding Quartzite. No uranium minerals were visible but radioactivity appears to be associated with limonite staining and carbonaceous matter in the form of fish scales and asphaltic pellets. An unidentified copper mineral was present in places.

## SAN JUAN COUNTY

The production of uranium from the county has been relatively large. However, it has been from only one mine. The Graysill Mine produced 31,494 tons of ore that contained 51,012 lb of  $U_3O_8$ . The potential for more reserves of uranium to be found in the county is limited.

The county is in the center of the San Juan Mountains in the southwestern part of the state. Paleozoic and Precambrian rocks crop out in the southern part of the county. A majority of the county is covered by Tertiary volcanic rocks associated with the San Juan Mountain Uplift. Large caldera systems are associated with the volcanic activity. These systems are important because of the base- and precious-metal mining associated with them. Mining for silver and gold has been important in the county since the late 1800's.

Two mines in the county have produced  $U_3O_8$  -- the Elk Park Prospect and the Graysill Mines. Although Elk Park Mine is a very minor producer of uranium, it is important from the standpoint of being a polymetallic type of uranium occurrence. Cobalt, silver and arsenic are associated with uranium in

the mine, making this one of the few mines of this type in Colorado. The Graysill Mine is a sandstone-type of uranium occurrence. The ore occurs in the Jurassic Entrada Sandstone. This is one of the Entrada roscoelite-type deposits that form a north-south belt from the Rifle Mine in Garfield County to the Good Hope-Nevada Group in La Plata County. This type of deposit is typified by primary vanadium and uranium as its by-product. The vanadium mica roscoelite is always in abundance at these deposits, and the Entrada Sandstone is the main host.

The potential for more reserves to be found in the county is small. The Graysill Mine has been closed for a number of years. The majority of the county is covered by volcanics, and, to date, these types of rocks have not been uranium producers, although uranium mineralization has been noted in volcanogenic rocks in other areas. Studies are now being carried out on this type of mineralization. Areas near calderas such as the Silverton could someday become potential host rocks after more research into this type of uranium occurrence. Also, the mineralization at the Elk Park is extremely interesting but appears to be limited.

## SAN MIGUEL COUNTY

San Miguel County lies within the Uravan mineral belt. Production from the county has been large and will continue to be so.

Production from January 1, 1948 to January 1, 1978 was 3,722,900 tons mined with 15,889,200 lb of  $U_3O_8$  produced at a grade of 0.21 percent  $U_3O_8$ . Of the tons mined, 3,720,000 tons were processed for vanadium and produced 177,416,000 lb  $V_2O_5$  at a grade of 1.58 percent  $V_2O_5$ .

The county lies on the Utah-Colorado border in southwestern Colorado and is underlain by flat-lying Cretaceous and Jurassic sediments. Volcanic rocks associated with the San Juan Mountain Uplift cover much of the eastern panhandle. The major structure in the county is the Big Gypsum Valley Anticline, a breached salt uplift.

Because of the production from the Uravan belt, the county is a major uranium producer in the state.

However, a second district separate from the Uravan district has produced uranium. This is the Placerville district in the eastern part of the county. Around the town of Placerville, uranium is associated as a by-product with vanadium in bedded deposits within the Jurassic Entrada Sandstone. This district is part of a large roscoelite belt that stretches from the Rifle Mine in Garfield County to the Good Hope-Nevada Group of claims in La Plata County. All along this belt the Entrada Sandstone contains tabular ore bodies in which roscoelite is always associated with uranium and vanadium minerals. The uranium in these deposits has a grade of about 0.05 percent  $U_3O_8$  and vanadium averages 1 to 1.5 percent  $V_2O_5$ . Mining is not being carried out at this time.

Reserves in the county are fairly large, and the potential is excellent for more to be found. Production in the county will continue for years to come.

## SEDGWICK COUNTY

There are no reported occurrences of uranium in this county.

The geology of the county is very simple, consisting of flat-lying Tertiary and Quaternary sediments.

Potential for uranium resources in the county is small. The Ogallala Formation is the most favorable unit in the county for such resources.

## SUMMIT COUNTY

No recorded production of uranium is reported in Summit County. Only three occurrences of uranium have been reported in the county, and the validity of one is questionable.

Geologically, the county is quite complex. Its southern part lies astride the Colorado mineral belt in the Park Range and includes the mining districts of Breckenridge, Montezuma, and Kokomo. The northern half includes the Gore Range and the Williams Forks Mountains separated by the valley of the Blue River.

Precambrian, Paleozoic, and Tertiary rocks are intermingled in all of the mountain ranges. Quaternary and Cretaceous rocks are found in the valley of the Blue River.

Potential for reserves to be found in the county appears to be small, due to the unfavorable host-rock types that occur in the county. Because of the complexity of structures and intrusions, the most likely occurrences that would be found in the county would be the vein-type or igneous-type.

## TELLER COUNTY

Little uranium has been produced from Teller County. Records show that by 1971, 401 tons of ore were mined that yielded 1,226 lb of  $U_3O_8$ .

The geology of the county is not complex. It is almost entirely underlain by Precambrian igneous rocks, mostly the Pike's Peak Granite. Scattered volcanics are found in the southern part of the county, and some Tertiary lake beds lie along the western edge. A large graben near the town of Woodland Park has preserved Cambrian to Mississippian sediments. Uranium occurrences are recorded in almost all these rock types, except for the Paleozoic sediments found in the graben.

Only five mines or prospects out of 13 total uranium occurrences in the county have recorded uranium production. All of these mines have produced from one formation, the Tallahassee Creek Conglomerate. The producing mines include Abril 2, 6, 8, Genevieve Lode, High Park Prospect, McVey Lease, and SWQ NEQ, sec. 36. Three of these producers are clustered in the southwestern corner of the county. One is on Grouse Mountain southwest of Victor. The other producing mine is near Rhyolite Mountain north of the town of Cripple Creek. Those three producers all occur in the Tertiary Tallahassee Creek Conglomerate in an area known as High Park. This area was extensively explored in the 1950's, and recent exploration carried out by Cyprus Mines has found economic reserves at the High Park Prospect. In 1977 a small pilot open pit was under development at this site to test the feasibility of mining. Mining at High Park Prospect is planned to commence at the same time the Hansen Ore Body at Tallahassee Creek in Fremont County begins production.

The SWQ NEQ, sec. 36 mine on Grouse Mountain has produced approximately 76 percent of the recorded tonnage mined for uranium in the county. This mine also is reported to be in the Tallahassee Creek Conglomerate.

The last-mentioned producer is the Genevieve Lode north of Cripple Creek. It is reported to occur in Tertiary volcanics, tuffs, and in a conglomeratic sandstone possibly within the Tallahassee Creek Conglomerate.

The potential for more reserves to be found in the county is high. All producing mines in Teller County are within the Tallahassee Creek Conglomerate, which is the host for the large Hansen Ore Body in the Tallahassee Creek area. Therefore, this formation will become a high-priority exploration target. Other rock showing potential are the Florissant lake beds. These sediments were explored near the towns of Divide and Lake George (Del Rio, 1960, p. 364) in the 1950's. Exploration was also carried out at these localities in 1976-77. It is very likely that these areas contain uranium reserves, but we were not able to document them. Another potential host for uranium resources in the county is the Mt. Rosa alkaline granite, a series of granitic bodies that extend from Teller into El Paso County. A number of occurrences associated with this granite are noted in El Paso County with one in Teller County. The areas where this granite is sheared and/or altered have potential for uranium occurrences and resources. For more information on this particular host see Murphy, M., Wollenberg, H., Strisower, B., and others, 1978, Uranium in Alkaline Rocks, U.S. Department of Energy GJBX078(78), p. 50.

Uraninite and uranothorite are found in small pegmatites within the Pike's Peak Granite. However, these are too small to be considered economic.

In conclusion, rock types and structures in the county have potential for hosting uranium resources. The small historical production belies the future potential for uranium resources in the county.

## WASHINGTON COUNTY

Neither uranium production nor occurrences have been reported from this county. The county is underlain by flat-lying Quaternary and Tertiary sediments. Potential for uranium resources within the county is small, but the most favorable unit for occurrences is the Tertiary Ogallala Formation, which outcrops in the eastern area of the county.

## WELD COUNTY

No production of uranium from Weld County has taken place to date. Production will begin in the near future as Power Resources Corporation and Wyoming Minerals Corporation develop their in-situ leach project near the communities of Grover and Keota.

Weld County is in northeastern Colorado in the Great Plains Province. Upper Cretaceous sedimentary rocks dip gently southwest into the Denver Basin. The bedrock formations are mantled extensively by Tertiary gravels and clays and Quaternary eolian sands and valley-fill deposits.

Exploration in the northern part of the Denver Basin for uranium has been underway since 1970. Occur-

rences in outcrops of the Laramie Formation caused accelerated exploration, and subsequent wide-spaced drilling discovered several deposits. These deposits occur in what may be unaltered beach sands in the Laramie Formation, very similar to the uranium deposits in Texas. The deposit near Grover was chosen as an in-situ leach test site. The pilot test of this program is in operation at this time. Reserves at the Grover site have been reported to be about 1,000,000 lb of  $U_3O_8$  (Reade, H. L., 1976). Other deposits of this type will likely be discovered in the county. The 30 occurrences in the county almost all lie in the Laramie or Fox Hills Formations.

## YUMA COUNTY

There has been no production of uranium from Yuma County, nor are any occurrences reported.

The geology of the county is simple, consisting of flat-lying Quaternary, Tertiary, and Cretaceous sediments.

Potential for uranium resources in the county is small. The Tertiary Ogallala Formation is the most favorable unit for uranium occurrences.

## **PART TWO**

### **Bibliography**

## Introduction

This bibliography is a compilation of references dealing with radioactive occurrences and radioactivity in Colorado. We have attempted to make it complete as of approximately October 1977, with more recent references added as they came to our attention. Obviously a "complete" bibliography is virtually impossible, but this work is as comprehensive as we could achieve within the given time constraints. Readers' contributions of any additional references will be added to our files.

### DESCRIPTION OF COMPILATION METHODS, STYLE AND FORMAT

References were compiled from a large variety of sources and entered in a standard format onto a mini-computer. The format chosen was taken from "Suggestions to Authors", 5th edition, 1958, by the U.S. Geological Survey. The references are arranged alphabetically by the first author's last name, and then by additional authors where they exist. This alphabetization was done by computer and carries to 28 places. When an author has written more than one paper, the references are arranged chronologically. Each reference includes the author's name(s), year of publication, title of the article, publication source, and number of pages:

Shoemaker, E. M., and Newman, W. L.,  
1957, Notes on the Moenkopi  
Formation in the salt anticline  
region of Colorado and Utah: U.S.  
Geol. Survey T-681, 43 p., (see  
Am. Assoc. Petroleum Geologists  
Bull., v. 43, p. 1835-1851).

The names of serial publications are abbreviated but are listed in full in the serials list at the beginning of the bibliography. Cross-references, where known to us, are shown in parentheses with each reference (see example), so that if one publication is unobtainable, the same or similar information may be found in another journal or book.

### DESCRIPTION OF SOURCES

Sources of information include published and unpublished bibliographies, computerized bibliographic searches, state and federal libraries and librarians, and miscellaneous references furnished by many people who have helped in completing the project. The U.S. Geological Survey Library in Lakewood, Colorado was the main reference facility used, with some additional work done at the Department of Energy Library in Grand Junction, Colorado and at the Colorado State Library in Denver, Colorado. The primary literature sources include:

Several types of references need some explanation for those who are not already familiar with them. These include Trace Elements Investigations Reports (TEI), Trace Elements Memorandum Reports (TEM), Raw Materials Exploration Reports (RME) and Raw Materials Operations Reports (RMO).

Trace Elements Investigations reports (TEI) and Trace Elements Memorandum reports (TEM) resulted from investigations conducted by the U.S. Atomic Energy Commission and/or the U.S. Geological Survey,

primarily during the 1950's. Raw Materials Exploration Reports (RME) and Raw Materials Operations Reports (RMO) were issued by the Division of Raw Materials of the Atomic Energy Commission. All of these reports concerned investigations of and for defense-related minerals--primarily uranium, thorium, and beryllium. The reports were not originally intended for public inspection and were considered "classified" or for "official use only". When information contained in these reports was to be made public, it was published in journal articles or other forms such as U.S. Geological Survey Circulars, Bulletins, Professional Papers, and Open-file reports. Where known, the reference to the published form of these previously classified reports is given as a note following each individual reference in this bibliography.

In 1975 the U.S. Geological Survey reviewed and declassified many of the older TEI's and TEM's. However, some 350 of these reports remained classified as "official use only". In response to requests resulting from this current study, the majority of the remaining 350 classified reports are being or have been declassified. Microfiche copies of these will soon be available for public inspection at various federal government depositories. Since declassification is nearing completion, we have included references to these reports.

#### USE OF THE BIBLIOGRAPHY

The bibliography volume is broken into two major sections: the bibliographic references and the cross-indexes. The references are presented first and have already been described partially as to style and format. The cross-indexes follow the references and are divided into the general categories of county and host rock, and the special categories of "Colorado Plateau", "Front Range", and "thorium".

The bibliography primarily includes references to specific information on uranium or other radioactive minerals in Colorado. Some reports, however, contain only general reference to uranium and uranium geology, applicable to Colorado as well as to other uranium-producing states. A few references contain no information on uranium but deal with geographic areas or deposits in which uranium has been found in significant amounts.

Keywords were assigned to each reference in the bibliography and were determined by consulting the individual reports or their abstracts when possible. Most of the reports deal with specific deposits or localities within Colorado and, therefore, include information on counties and host rocks. All reports were specifically keyworded and cross-indexed for these two subjects, with additional keywords added as known and appropriate. The generalized host rock type names which were used for the cross indexing include:

coal, shale  
igneous-metamorphic  
limestone, phosphorite  
sandstone, siltstone  
spring deposits, groundwater

If the report was unlocatable or unobtainable, the keywords were taken from the title of the report.

Some reports of a general nature discuss only such larger provinces as the "Colorado Plateau" or the "Front Range" and do not cite specific counties or host rocks. These reports were included in the cross-index as special categories since they are major uranium provinces in Colorado. When specific locations could be inferred from these general citations, the appropriate county and host-rock keywords were added to facilitate retrieval by the cross-indexes.

Stratigraphic nomenclature used in keywording is taken from many sources and from references written over a period of years; therefore, certain nomenclature may be outdated. We sought to make the names consistent as the entries were keyworded. As a result, names like "Entrada sandstone", "Entrada Formation", "Entrada Sandstone", and "Entrada formation" have all been standardized to "Entrada Sandstone" in the keywording. Also, if old nomenclature was used in the reports, and if the currently accepted formation names were known, both terms were used in keywording the entries.

To use the cross-indexes, first look for the county, host rock, or special category in which you are interested. For example, if you want information on Lake County, turn to the cross-index for Lake County to find:

#### LAKE COUNTY

Pierson, C. T., and Singewald, Q. D., 1953  
Sugar Loaf district/St. Kevin district/  
Lake County/ igneous-metamorphic/

geology/ veins/ minerals/ autunite/  
florencite/ metatorbernite/ torbernite/  
Josie May mine/ Turquoise Chief mine/  
granite/ turquoise/ Wilkesbarre adit/  
mineralogy/ leaching/Precambrian rocks/  
Tertiary/ schist/

This report discusses deposits in Lake County, with information on all of the other subjects in the keywords. Note that this reference would also be listed under the host-rock cross-index for "igneous-metamorphic". If the subjects listed within the keywords describe a reference of interest, turn to the bibliography and look for the author's name(s):

Pierson, C. T., and Singewald, Q. D., 1953,  
Occurrences of uranium-bearing  
minerals in the St. Kevin district,  
Lake County, Colorado: U.S. Geol.  
Survey TEI-234, 39 p., maps. (see  
U.S. Geol. Survey Bull. 1027-E).

This reference is one of the TEI's, which are sometimes difficult to obtain. In this case, because of the cross-reference, the U.S. Geological Survey Bulletin that should contain similar or identical information can easily be obtained from any major library.

We hope that you will find the bibliography and cross-indexes both useful and easily useable, as these were two of the major goals in compiling them. If the general features and limitations of each are kept in mind, we think that they can be valuable tools for geologists, explorationists, planners, government officials, students, and many others, for years.

## Serials List

Acad. Nat. Sci. Philadelphia Proc. ....	Academy of Natural Sciences of Philadelphia Proceedings. Philadelphia, Pennsylvania.
Acta Cryst. ....	Acta Crystallographica (International Union of Crystallographica). Copenhagen.
Akad. Nauk SSSR Inst. Geologii Rudnykh Mestorozhdeniy, Petrografi, Mineralogii i Geokhimii. ....	Akademlya Nauk S.S.S.R. Institut Geologii Rudnykh Mestorozhdenii, Petrografi, Mineralogii: Geokhimii.
Akad. Nauk SSSR Izv. Ser. Geol. ....	Akademlya Nauk S.S.S.R. Izvestiya. Seriya Geologicheskaya.
Akad. Sci., Comptes Rendus ....	Akademlya Nauk S.S.S.R. Science, Comptes Rendus.
Am. Assoc. Petroleum Geologists Bull. ....	American Association of Petroleum Geologists, Bulletin. Tulsa, Oklahoma.
Am. Assoc. Petroleum Geologists, Geol. Record. ....	American Association of Petroleum Geologists, Geologic Record.
Am. Assoc. Petroleum Geologists Mem. ....	American Association of Petroleum Geologists, Memoir. Tulsa, Oklahoma.
Am. Geophys. Union Trans. ....	American Geophysical Union, Transactions. Washington, D.C.
Am. Inst. Mining and Metallurgical Engineers, Mining Geology, Geophysics Div. Ann. Mtg., Abs. Tech. Papers. ....	American Institute of Mining and Metallurgical Engineers, Mining Geology, Geophysics Division Annual Meeting, Abstract of Technical Papers.
Am. Inst. Mining Eng. Trans. ....	American Institute of Mining Engineers Transcript.
Am. Inst. Mining, Metallurgical, and Petroleum Engineers, Ann. Minerals Symposium. ....	American Institute of Mining, Metallurgical and Petroleum Engineers, Annual Minerals Symposium.
Am. Jour. Sci. ....	American Journal of Science. New Haven, Connecticut.
Am. Mineralogist. ....	American Mineralogist (Mineralogical Society of America, Journal). Washington, D.C.
Am. Mining Cong., Ann. Rpt. Proc. ....	American Mining Congress, Annual Report of Proceedings.
Am. Mus. Nat. History Bull. ....	American Museum of Natural History, Bulletin. New York.
Am. Philos. Soc. Proc. ....	American Philosophical Society, Proceedings. Philadelphia, Pennsylvania.
American Assoc. Adv. Sci. Proc. ....	American Association for the Advancement of Science Proceedings, Washington, D.C.
Anal. Chemistry ....	Analytical Chemistry.
Arch. Ind. Health ....	Archives of Industrial Health.
Arizona Bur. Mines Bull. ....	Arizona Bureau of Mines, Bulletin.
Atom - U.S. ....	Atom - United States.
Austria, Z. Bergwirtsch. Huettenwes. ....	Austria, Z. Bergwirtsch. Hue Huettenwes.
Bull. Atomic Scientists ....	Bulletin of Atomic Scientists.
Bull. Volcanol. ....	Bulletin of Volcanology.
California Div. Mines ....	California Division of Mines.
California Inst. Technology ....	California Institute of Technology.
Canada Inst. Mining Metall., Geol. Div., Soc. Econ. Geology ....	Canadian Institute of Mining and Metallurgy, Geological Division, Society of Economic Geology.
Canadian Mineralogist ....	Canadian Mineralogist.
Canadian Mining Metall. Bull. ....	Canadian Mining and Metallurgy, Bulletin.
Chem. Abs. ....	Chemical Abstracts.
Chemical News ....	Chemical News.
Chemikerzeitung ....	Chemikerzeitung.
Colorado Basic Data Report ....	Colorado Basic Data Report.
Colorado Bur. Mines Circ. ....	Colorado Bureau of Mines, Circular. Denver, Colorado.
Colorado Bur. Mines Pub. ....	Colorado Bureau of Mines, Publication.
Colorado Bur. Mines Rept. ....	Colorado Bureau of Mines, Report.
Colorado Geol. Survey Bull. ....	Colorado Geological Survey, Bulletin. Denver, Colorado.
Colorado Geol. Survey Inf. Ser. ....	Colorado Geological Survey, Information Series. Denver, Colorado.
Colorado Geol. Survey Map Ser. ....	Colorado Geological Survey, Map Series. Denver, Colorado.
Colorado Magazine. ....	Colorado Magazine.
Colorado Metal Mining Fund ....	Colorado Metal Mining Fund.

Colorado Mineral Resources Board .....	Colorado Mineral Resources Board.
Colorado Mining Assoc. Mining Yearbook .....	Colorado Mining Association Mining Yearbook.
Colorado Mining Assoc., Nat'l. Western Mining Conf. Trans. ....	Colorado Mining Association, National Western Mining Conference Transcript.
Colorado Mining Assoc. Spec. Pub. ....	Colorado Mining Association Special Publication.
Colorado School Mines .....	Colorado School of Mines. Golden, Colorado.
Colorado School Mines, Bienn. Report .....	Colorado School of Mines Biennial Report. Golden, Colorado.
Colorado School Mines Mineral Industries Bull. ....	Colorado School of Mines Mineral Industries Bulletin. Golden, Colorado.
Colorado School Mines Progress Rpt. ....	Colorado School of Mines, Progress Report. Golden, Colorado.
Colorado School Mines Quart. ....	Colorado School of Mines, Quarterly. Golden, Colorado.
Colorado School Mines Remote Sensing Rpt. ..	Colorado School of Mines Remote Sensing Report. Golden, Colorado.
Colorado School Mines Research Foundation, Inc. ....	Colorado School of Mines, Research Foundation Incorporated. Golden, Colorado.
Colorado School Mines, Unpub. notes .....	Colorado School of Mines, Unpublished Notes. Golden, Colorado.
Colorado Sci. Soc. Proc. ....	Colorado Scientific Society, Proceedings. Denver, Colorado.
Colorado Water Conserv. Board Ground Water Ser. Basic Data Rpt. ....	Colorado Water Conservation Board Ground Water Series Basic Data Report.
Commonwealth Mining and Metal. Cong., Proc., Inst. Mining and Metallurgy.....	Commonwealth Mining and Metallurgy, Congress, Proceedings, Institute of Mining and Metallurgy.
Compass.....	Compass of Sigma Gamma Epsilon. Lawrence, Kansas.
Comptes Rendus.....	Comptes Rendus.
Contributions to Geology.....	Contributions to Geology (Wyoming University). Laramie, Wyoming.
Dallas Dig. ....	Dallas Digest.
Denison Univ. Sci. Lab. Jour. ....	Denison University, Journal of Scientific Laboratories. Granville, Ohio.
Denver Magazine.....	Denver Magazine.
Dissert. Abs. Internat. ....	Dissertation Abstracts International; Abstracts of Dissertation Available on Microfilm or as Xerox Reproductions. Ann Arbor, Michigan.
Earth Science Bull. ....	Earth Science Bulletin (Wyoming Ecological Association). Casper, Wyoming.
Econ. Geology.....	Economic Geology and the Bulletin of the Society of Economic Geologists. New Haven, Connecticut.
Eng. and Mining Jour. ....	Engineering and Mining Journal. New York.
Explosives Engineer.....	Explosives Engineer.
Four Corners Geol. Soc. Field Conf. ....	Four Corners Geological Society Field Conference.
Four Corners Geol. Soc. Guidebook.....	Four Corners Geological Society Guidebook.
Fuel.....	Fuel; the Journal of Fuel Science. London.
Geochim. et Cosmochim. Acta.....	Geochimica et Cosmochimica Acta (The Geochemical Society, Pergamon Press, Oxford.
Geol. Soc. America Abs. with Programs.....	Geological Society of America, Abstracts with Programs.
Geol. Soc. America Bull. ....	Geological Society of America, Bulletin. Boulder, Colorado.
Geol. Soc. America Mem. ....	Geological Society of America, Memoir. Boulder, Colorado.
Geol. Soc. America Spec. Paper.....	Geological Society of America, Special Paper. Boulder, Colorado.
Geophysics.....	Geophysics (Society of Exploration Geophysicists, Journal). Tulsa, Oklahoma.
Globus.....	Globus.
Health Physics.....	Health Physics.
Idaho Mineral Industries Ann. Rpt. ....	Idaho Mineral Industries Annual Report.
Inst. Geol., Anu.....	Institutul de Geologie si Geofizica. Darl de Seama Ale Sedintelor. Romania.
Intermtn. Assoc. Geologists Ann. Field Conf. ....	Intermountain Association of Geologists Annual Field Conference.
Intermtn. Assoc. Petroleum Geologists Ann. Field Conf. Guidebook .....	Intermountain Association of Petroleum Geologists Annual Field Conference Guidebook.

Internat. Atomic Energy Agency Symposium.....	International Atomic Energy Agency Symposium.
Internat. Geol. Cong. ....	International Geological Congress.
Internat. Geology Review.....	International Geology Review.
Internat. Mineralog. Assoc. ....	International Mineralogical Association.
Isochron West.....	Isochron/West; a Bulletin of Isotopic Geochronology. Socorro, New Mexico.
Jour. Geology.....	Journal of Geology. Chicago, Illinois.
Jour. Geophys. Research.....	Journal of Geophysical Research (American Geophysical Union). Washington, D.C.
Jour. Metals.....	Journal of Metals.
Jour. Sed. Petrology.....	Journal of Sedimentary Petrology. Tulsa, Oklahoma.
Kansas Geol. Soc. Guidebook.....	Kansas Geological Society Guidebook.
Los Alamos Scientific Lab. Report NTIS # LA..	Los Alamos Scientific Laboratory Report National Technical Information Service. LA.
M.S.S. Report.....	Master of Social Studies Report.
Metallurgia.....	Metallurgia.
Mineral Industries.....	Mineral Industries Bulletin.
Mines and Mineral Reports of Colorado.....	Mines and Mineral Reports of Colorado.
Mines and Minerals.....	Mines and Minerals.
Mines and Minerals, Quart. Jour. Indian Bur. Mines, Nagpur, India.....	Mines and Minerals; Quarterly Journal of the Indian Bureau of Mines. Nagpur.
Mine & Quarry Eng. ....	Mine and Quarry Engineering.
Mines Mag. ....	Mines Magazine. Golden, Colorado.
Mining and Contracting Review.....	Mining and Contracting Review.
Mining Cong. Jour. ....	Mining Congress Journal.
Mining Eng. ....	Mining Engineering, American Institute of Mining Metallurgical and Petroleum Engineers. New York.
Mining Mag. ....	Mining Magazine. London.
Mining Rev. ....	Mining Review.
Mining Sci. ....	Mining Science.
Mining Sci. Press.....	Mining and Scientific Press. San Francisco, California.
Mining World.....	Mining World. San Francisco, California.
Moscow Atomizdat.....	Moscow Atomizdat.
Mtn. Geologist.....	Mountain Geologist (Rocky Mountain Association of Geologists). Denver, Colorado.
NASA Rept. ....	National Aeronautics and Space Administration Report.
Natl. Geog. Mag. ....	National Geographic Magazine (National Geographic Society). Washington, D.C.
Natl. Research Council Pub. ....	National Research Council Publication.
Natl. Tech. Inf. Service Pub. PB _____ Natl. Sci. Found. ....	National Technical Information Service, Publication of the National Science Foundation.
Natl. Tech. Inf. Service Pub. PB _____ U.S. Geol. Survey ....	National Technical Information Service, Publication of the U.S. Geological Survey.
New Mexico Bur. Mines and Mineral Resources..	New Mexico Bureau of Mines and Resources. Campus Station, Socorro, New Mexico.
New Mexico Geol. Soc. Field Conf. Guidebook..	New Mexico Geological Society, Annual Field Conference Guidebook. Socorro, New Mexico.
New Mexico Univ. Pubs. Geology.....	New Mexico University Publications Geology.
NSA.....	Nuclear Science Abstracts.
Nuclear Eng. Sci. Cong., Proc. ....	Nuclear Engineering Science Congress, Proceedings.
Nuclear Sci. ....	Nuclear Science.
Nucleonics.....	Nucleonics.
Oak Ridge National Lab. ORNL.....	Oak Ridge National Laboratory. Oak Ridge, Tennessee.
Oil and Gas Jour. ....	Oil and Gas Journal. Tulsa, Oklahoma.
Ores and Metals.....	Ores and Metals.
Pan-American Geology.....	Pan America Geology. Des Moines, Iowa.
Periodical Geology and Metallurgy.....	Periodical Geology and Metallurgy.
Precambrian.....	Precambrian.
Rocks and Minerals.....	Rocks and Minerals. Peetsville, New York.
Rocky Mtn. Assoc. Geologists Guidebook.....	Rocky Mountain Association of Geologists Field Conference Guidebook. Denver.
Schweiz. Mineralog. U. Petrogr. Mitt. ....	Schweizerische Mineralogische und Petrographische Mittellungen--Bulletin Suisse de Mineralogie et Petrografia Zuerich.
Science.....	Science (American Association for the Advancement of Science). Washington, D.C.

Ser. Hydrol., France, Office Recherches Sci.	
Tech. Outre-Mer, Cah. ....	Serie Hydrogeologie, France, Office de Recherches Scientifique et Technique, Outre-Mer, Cah.
Soc. Chim. de Paris Bull. ....	Societe de Chimie de Paris, Bulletin.
Soc. Francaise Mineralogie Bull. ....	Societe Francaise de Mineralogie et de Cristallographie, Bulletin. Paris.
Soc. Mining Bull. ....	Society of Mining, Bulletin.
Soil Sci. ....	Soil Science, Williams & Wilkins Co., Baltimore, Maryland.
Tech. Inf. Service CU ....	Technical Information Service. Colorado University.
Tschermaks Mineralogy Petrog. Mitt. ....	Tschermaks Mineralogische und Petrographische Mitteilungen. Vienna.
U. K. Atomic Energy Authority ....	United Kingdom Atomic Energy Authority.
U.N. Internat. Conf. on Peaceful Uses of Atomic Energy, Proc. ....	United Nations International Conference on Peaceful Uses of Atomic Energy, Proceedings.
Uranium ....	Uranium.
Uranium Pubs. ....	Uranium Publications.
U.S. Atomic Energy Comm. AEC-RD. ....	U.S. Atomic Energy Commission Report, AEC-RD.
U.S. Atomic Energy Comm. AEC-RID ....	U.S. Atomic Energy Commission Report, AEC-RID.
U.S. Atomic Energy Comm. CEX ....	U.S. Atomic Energy Commission Report, CEX.
U.S. Atomic Energy Comm. COM ....	U.S. Atomic Energy Commission Report, COM.
U.S. Atomic Energy Comm. COO ....	U.S. Atomic Energy Commission Report, COO.
U.S. Atomic Energy Comm. DAO-3-TM ....	U.S. Atomic Energy Commission Report, DAO-3-TM.
U.S. Atomic Energy Comm. DEB-3-TM ....	U.S. Atomic Energy Commission Report, DEB-3-TM.
U.S. Atomic Energy Comm. GJO ....	U.S. Atomic Energy Commission Report, GJO.
U.S. Atomic Energy Comm. open-file map ....	U.S. Atomic Energy Commission open-file map.
U.S. Atomic Energy Comm. open-file report ...	U.S. Atomic Energy Commission open-file report.
U.S. Atomic Energy Comm. PB ....	U.S. Atomic Energy Commission Report PB.
U.S. Atomic Energy Comm. Prelim. Map ....	U.S. Atomic Energy Commission Preliminary Map.
U.S. Atomic Energy Comm. Press Release ....	U.S. Atomic Energy Commission Press Release.
U.S. Atomic Energy Comm. RCD ....	U.S. Atomic Energy Commission Report RCD.
U.S. Atomic Energy Comm. Report ....	U.S. Atomic Energy Commission Report.
U.S. Atomic Energy Comm. RME ....	U.S. Atomic Energy Commission Report of the Raw Materials Division, RME.
U.S. Atomic Energy Comm. RMO ....	U.S. Atomic Energy Commission Report of the Raw Materials Division, RMO.
U.S. Atomic Energy Comm. TID ....	U.S. Atomic Energy Commission Report TID.
U.S. Atomic Energy Comm. TM ....	U.S. Atomic Energy Commission Report TM.
U.S. Atomic Energy Comm. Uranium Workshop ...	U.S. Atomic Energy Commission, Uranium Workshop.
U.S. Atomic Energy Comm. WASH ....	U.S. Atomic Energy Commission Report, Washington, D.C., WASH.
U.S. Bur. Indian Affairs Admin. Rept. ....	U.S. Bureau of Indian Affairs Administration, Report.
U.S. Bur. Mines Bull. ....	U.S. Bureau of Mines, Mines Bulletin. Washington, D.C.
U.S. Bur. Mines Inf. Circ. ....	U.S. Bureau of Mines, Information Circular. Washington, D.C.
U.S. Bur. Mines Mineral Resources U.S. ....	U.S. Bureau of Mines and Mineral Resources in the U.S.
U.S. Bur. Mines Rept. Inv. ....	U.S. Bureau of Mines, Report of Investigations. Washington, D.C.
U.S. Bur. Mines TPR ....	U.S. Bureau of Mines Report TPR.
U.S. Dept. Energy GJT ....	U.S. Department of Energy Report GJT. Grand Junction, Colorado.
U.S. Dept. Interior Press Memo ....	U.S. Department of the Interior, Press Memo.
U.S. 88th Cong. 2d sess., Comm. Print ....	U.S. 88th Congress, 2nd session, [Commission Print].
U.S. Energy Research Devel. Adm. ERDA ....	U.S. Energy Research and Development Administration Report ERDA.
U.S. Energy Research Devel. Adm. GJBX ....	U.S. Energy Research and Development Administration Report GJBX. Grand Junction, Colorado.
U.S. Energy Research Devel. Adm. GJO ....	U.S. Energy Research and Development Administration Report GJO. Grand Junction, Colorado.
U.S. Environmental Protection Agency Conf. ..	U.S. Environmental Protection Agency, Conference.
U.S. Environmental Protection Agency, Office Water Program ....	U.S. Environmental Protection Agency, Office Water Program.
U.S. Environmental Protection Agency PB ....	U.S. Environmental Protection Agency Report PB.
U.S. Environmental Protection Agency Radiation Data and Repts. ....	U.S. Environmental Protection Agency Radiation Data and Reports.
U.S. Govt. Printing Office ....	U.S. Government Printing Office.
U.S. Natl. Mus. Proc. ....	U.S. National Museum, Proceedings. Washington, D.C.

U.S. Geol. and Geog. Terr. Survey (Hayden)	
Ann. Rept. ....	U.S. Geologic and Geographic Territorial Survey (Hayden) Annual Report.
U.S. Geol. Survey Bull. ....	U.S. Geological Survey, Bulletin.
U.S. Geol. Survey Circ. ....	U.S. Geological Survey, Circular.
U.S. Geol. Survey Geol. Quad. Map GQ ....	U.S. Geological Survey, Geologic Quadrangle Map.
U.S. Geol. Survey Geophys. Inv. Map GP ....	U.S. Geological Survey, Geophysical Investigations Map.
U.S. Geol. Survey Jour. Research ....	U.S. Geological Survey, Journal of Research.
U.S. Geol. Survey leaflet ....	U.S. Geological Survey, leaflet.
U.S. Geol. Survey Mineral Inv. Field Studies	
Map MF ....	U.S. Geological Survey, Mineral Investigations, Field Studies Map.
U.S. Geol. Survey Mineral Inv. Resource Map	
MR ....	U.S. Geological Survey, Mineral Investigations Resource Map.
U.S. Geol. Survey Mineral Resources U.S. ....	U.S. Geological Survey, Mineral Resources of the U.S.
U.S. Geol. Survey Minerals Inv. Prelim. Map	U.S. Geological Survey Minerals Investigations, Preliminary Map.
U.S. Geol. Survey Misc. Geol. Inv. Map I ....	U.S. Geological Survey, Miscellaneous Geologic Investigations Map.
U.S. Geol. Survey Missouri Basin Studies	
Map ....	U.S. Geological Survey Missouri Basin Studies Map.

## BOULDER COUNTY

Caribou mine/ Radium vein/ Igneous-metamorphic/  
uraninite/ Front Range/ Boulder County/

Wright, H. D., 1951

ore deposits/ paragenesis/ Boulder County/ Caribou  
district/ Radium vein/ Igneous-metamorphic/  
uraninite/ silver/ Caribou mine/ Front Range/  
veins/

Wright, H. D., 1951

Canada/ Ontario/ ore deposits/ uraninite/ Caribou  
mine/ alteration/ Boulder County/ paragenesis/  
Front Range/ Igneous-metamorphic/

Wright, H. D., 1954

ore deposits/ uraninite/ mineralogy/ Boulder  
County/ silver/ Radium vein/ uranium/ veins/  
wall-rock/ Igneous-metamorphic/ geochemistry/  
Caribou mine/ Front Range/ Caribou district/

Wright, H. D., and Shulhof, W. P., 1957

veins/ sulfide minerals/ Front Range/ Boulder  
County/ Igneous-metamorphic/ ore deposits/

Wyant, D. G., 1949

Boulder County/ Wheelman (mine) tunnel/ pegmatites/  
Igneous-metamorphic/ Precambrian rocks/ granite/  
gold/ wolframite/ veins/ Front Range/ analyses/

## CHAFFEE COUNTY

Adams, J. W., 1948

Chaffee County/ Gunnison County/ Mount Antero/  
Igneous-metamorphic/ beryl/ beryllium/ White  
Mountain/

Adams, J. W., 1951

Chaffee County/ Carbonate Mountain/ Garfield  
quadrangle/ Mount Antero region/ brannerite/  
California mine/ veins/ molybdenum/ pegmatites/  
Igneous-metamorphic/ aquamarine/ White Mountain/  
granite/ quartz monzonite/ beryllium/

Adams, J. W., 1953

veins/ pegmatite/ quartz/ beryllium/ Mount Antero/  
White Mountain/ granite/ quartz monzonite/ California  
mine/ brannerite/ aquamarine/ molybdenum/ Chaffee  
County/ Igneous-metamorphic/

Baillie, W. N., 1962

pegmatites/ feldspar/ rare earths/ Boulder County/  
Chaffee County/ Clear Creek County/ Douglas  
County/ El Paso County/ Fremont County/ Gunnison  
County/ Jefferson County/ Larimer County/ Park  
County/ Igneous-metamorphic/ Front Range/

De Voto, R. H., 1961

South Park/ Park County/ sandstone/ Chaffee  
County/ geology/ ore deposits/

De Voto, R. H., 1971

South Park/ Park County/ Chaffee County/ sandstone/  
geology/ geologic history/ Antero Reservoir  
quadrangle/ ore deposits/

Dings, M. G., 1952
