Acknowledgments

I would like to thank the staff of the Colorado Oil & Gas Conservation Commission (C.O.G.C.C.) who provided considerable assistance during the course of this compilation, and the staff of the Colorado Geological Survey, who assisted in the manuscript preparation.

However, I assume full responsibility for any errors or omissions in these tabulations. Users of this OPEN-FILE REPORT could provide a significant service if they would inform the Colorado Geological Survey of any misinformation or omissions.

This project was completed by the staff of the Colorado Geological Survey as part of a grant from the Department of Local Affairs - Division of Commerce and Development.

A. H. Scanlon Senior Geologist

Appendix I- Field-Horizon Historical Production Decline Curves for E	Baca County 8

Introduction

This report is the sixth* in a series of oil and gas reserve investigations undertaken for those counties in which oil and/or gas is currently being produced.

This study involves Baca County, located in the southeastern corner of Colorado. The eastern edge of this county is part of the Hugoton Embayment. Baca County covers 2,565 square miles. In this county, oil and/or gas are produced from, in descending order of age, the Red Cave (Lyons) Sandstone, Wabaunsee Carbonate, Topeka Carbonate, Lansing Limestone, Morrowan Sandstone and Keyes Sandstone.

There are 10 fields considered active producers as of September 30, 1983. Of these, 3 are classified as oil fields (based on cumulative gas-oil ratio (GOR) of <15:1), and 7 are classified as gas fields (based on cumulative GOR >15:1).

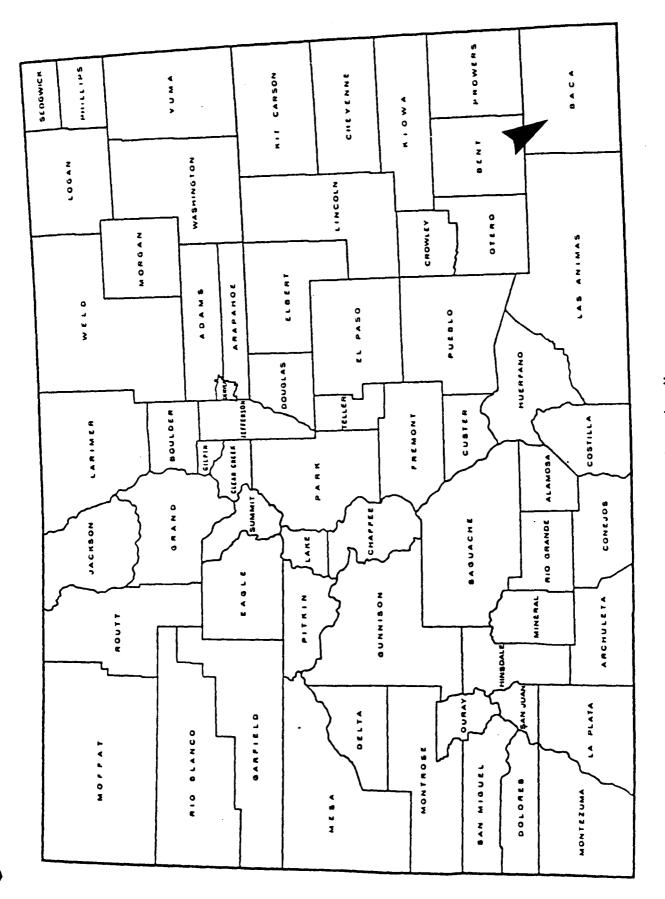

Figure 1. County Location Map

Method of Approach

Production decline curves are plotted for each currently producing horizon within each field, hereafter referred to as a field-horizon. There are 17 production decline curves plotted, one for each field-horizon. Production data were obtained from the C.O.G.C.C. annual production books. These books contain records of yearly production data, dating back to 1952. All production decline curves are plotted as rate (annual production in barrels of oil or MCF of gas) versus time (in years). The rate scale was adjusted to accommodate each field-horizon.

Oil Reserve Calculations

There are 4 oil field-horizons. Production histories have allowed for decline rates to be calculated for 3 of these. The remaining oil field-horizon has not produced for a long enough time (less than 1 year) to determine a reliable decline rate. For the previously mentioned 3 fields, decline rates were determined based on actual past production and recorded, see Table I. These decline rates were then applied to the equation:

Rr = q1 - qf
-ln (1-dy)

where: Rr = remaining reserves
q1 = current annual production
qf = final economic production rate
(see note below.)
-ln = negative natural log
dy = yearly decline rate (in percent)

The ultimate recoverable was then determined by adding the estimated reserves to the cumulative production. These values are listed in Table I.

Note: the final economic production rate used was one barrel of oil per day per well, for one year; therefore 365 barrels, multiplied by the number of wells needed to keep field production economic. In most cases this was one well. The number of wells used was determined at the discretion of the author.

For associated gas production, estimated reserves were calculated in the same manner as that described in the Gas Reserve Calculations section.

Gas Reserve Calculations

There are 13 gas field-horizons. Production histories have allowed for decline rates to be calculated for 9 of these. The remaining 4 gas field-horizons have not produced for a long enough time (less than 3 years) to determine a reliable decline rate. Decline rates were determined for the 13 previously mentioned field-horizons (see Table I) and applied to the equation:

 $S = a(1-r^n)$ Where: S = gas reserves $a = current \ annual \ gas \ production$ $r = (1-dy) \ where \ dy = annual \ decline \ rate$ $n = number \ of \ years \ -- 20 \ years \ was \ used$ $in \ all \ cases \ except \ where \ noted \ in$ $the \ remarks \ column \ of \ Table \ I.$

Results can be found in Table I.

For the associated oil production, where this production was significant, the same method to determine estimated oil reserves was used, as discussed in the previous section. Whether oil production was considered significant or not was determined by the author. In allicases, if oil production indicated any kind of trend, reserves were calculated. A few cases arose where oil production, though a trend was indicated, did not exceed the economic limit (as discussed previously) of one barrel of oil per day per year, and therefore no reserve estimate was calculated, or an economic limit of zero was used.

Results

The following figures are for those field-horizons for which reserves could be calculated. Estimated oil reserves for Baca County totaled 1,064,172 barrels. Estimated gas reserves for Baca County totaled 32,556,964 MCF. Note that the gas reserve calculations are based on a 20-year projection, therefore they do not account for gas production after the year 2002.

These figures also do not account for production increases due to secondary and/or tertiary recovery not already in progress, or account for undiscovered reserves, nor do they reflect changes in economics or demand.

In 11 to 12 years, roughly half of the estimated oil reserves in Baca County will have been produced. Roughly one half of the estimated gas reserves for the next 20-year period are expected to be produced in approximately four years.

In this county there are two classes of field-horizons: I) those with a long enough production history to calculate reserves with confidence, and II) those new field-horizons with essentially no production history, or for other reasons, reserves cannot be calculated.

To be able to calculate total county oil and gas reserves, it was necessary to apply the overall decline rates (5.6 percent per year for oil and 15.6 percent per year for gas) obtained from class I field-horizons to the current production from Class II field-horizons.

Using this approach on current production from Class II field-horizons (8,132 Bbls. of oil and 41,841 MCF of gas) additional reserves of 109,441 Bbls. of oil and 259,189 MCF of gas were obtained. This gives total county reserves (Class I and II) of 1,173,613 Bbls. of oil and 32,816,153 MCF of gas.

To insure that the reserve figures calculated for Class II are reasonable using this method, a comparison was made between the sources (producing horizons) of the Class I and Class II field-horizons. It was determined that there were some significant differences in the sources of production for the two groups. Therefore, it is concluded that the overall decline rates applied are somewhat questionable for the Class I estimated reserves.
