EXECUTIVE SUMMARY

This project was prepared through a grant from the Department of Local Affairs. The objective of this report is to forecast metal mining activity in Colorado to the year 2002. Forecasts are presented for seven metals including gold, silver, lead, zinc, copper, molybdenum, and uranium. Using production as the basis, projections of employment, wages and the amount of local purchases are also included.

Trend analysis is used as the forecasting method. It consists of fitting a curve to the historical data and then using the curve to forecast future values. This method provides reasonable projections based on project goals, time, and funding constraints.

The data for the project came from many sources as noted in Appendix C. The Colorado Division of Mines and the U.S. Bureau of Mines were the primary sources. Uranium data are derived from available DOE information. However, data from 1980 is not available, and will likely not be available in the future. Hence uranium was dropped from the metals that were forecasted.

Trend analysis was applied to total metal production at the county level, but gave poor results. Therefore, aggregate state level forecasts were prepared and then proportioned to each producing county. The resultant state forecasts and graph are shown in Appendix B. After curve fitting to a power five, a linear trend was chosen for the forecast. The trend of real dollars uses the slope of the linear trend calculated on the deflated dollars and the 1983 preliminary estimate from the USBM. This removes the effect of inflation on the value of metals over the period 1977 to 1981. Employment is projected using a constant rate that reflects productivity in Colorado over the last five years. Wages paid are calculated from the Mining Wage Index projected at a constant 5 percent growth rate. This wage rate is multiplied times the employment. The local purchases are a percent of production value. The percentage that is developed comes from a mine model that was developed on the two molybdenum mines in the state. This reflects the fact that 90 percent of the total state metal value is produced by the two mines.

Forecasts are usually incorrect and a method of using actual data as it becomes available each year to correct the forecast is always needed. A method is included to modify the forecast as data becomes available to measure the error. There are two points where errors are foreseeable. The forecast of the state total will be one source of errors and the ratios used to divide the total to the county level will be the other. The errors can be adjusted by changing the equation of the curve, and the ratios.

PURPOSE

This project is one of a series funded by the Department of Local Affairs. Their purpose is to forecast economic and demographic impacts of resource development at the county level in Colorado. This specific report forecasts metal production to the year 2002 for seven (7) metals. These metals are gold(au), silver(ag), copper(cu), lead(pb), molybdenum(mo) and zinc(zn). Because of the lack of data after 1980, it was decided to exclude uranium from the metals being forecasted. In addition to the production of these metals, there are three other related items that are forecasted. They are employment, wages paid, and local purchases by the companies producing the metals. These related items are projected using the metal forecasts as a basis for forecasting. The methodologies and the associated strengths and weaknesses are also discussed.

Originally the individual metals were to be forecasted on a county by county basis. After some work with the data it became apparent that using an aggregate method was the way the counties could be forecasted with better results. In carrying out the forecast, several assumptions are made about metal production in Colorado. These are noted in the Forecast Section.

ACKNOWLEDGEMENTS

I want to thank Al Hornbaker for his guidance and help during the writing of this report, Pat Rogers for his timely and useful suggestions. Bill Crowl made the paper more useful by suggestions during the draft stage of the report. Also, I want to thank Debra Tully for her comments about the forecasting tools used in the report.

Mr. Steve Colby of Department of Local Affairs contributed advice and suggestions during the course of the research. Mr. Ron Cattany of Department of Natural Resources edited the report and also contributed numerous suggestions.

REVIEW OF FORECAST OPTIONS

Several forecast methods were evaluated for this project. They were:

Quantitative

- econometric modelling
- input-output analysis
- resource analysis and modelling
- regression analysis
- time series analysis
- trend analysis

Qualitative

- delphi method
- technological forecasting

Econometric modelling and Input-Output analysis are ruled out because of the time and funds required by these complex methods. Resource analysis would have taken too much time and would have been one or two people's calculation of available resources. Also, it is a variant of the delphi method and should be carried out by a team. Regression is rated highly. Time series is concerned with the annual changes in the data due to the fluctuation of seasons parameters. Trend analysis, a variant of time-series analysis is recommended for a project of this type.

Trend analysis combines Time Series and Regression. It fits the data to a line by regression assuming that the independent variable is time. If long range (2 years +) accuracy is the primary need, the delphi method would have been recommended. Trend analysis was chosen because it is good for forecasting from short to medium term with historical data. It also can be carried out quickly and takes little resources in terms of time and money. It uses regression techniques to fit to the historical data. The disadvantage is that the method is poor for long term forecasts because it is not able to predict "turning points". These are points where a new idea or technology changes the way the trends are produced.

The 'delphi method' can be considered as an option; however, it is not a method that gives good numbers for short range forecasts. The delphi method on the other hand, is a very good technique for long range forecasts. It is a qualitative method that uses teams of experts to come to a consensus of the future for some subject. The resources required for the delphi method are 3-6 months time, and a panel of experts.

SUMMARY OF HISTORICAL DATA

The data used for the forecast came from several sources. All sources are noted in Appendix C. The Colorado Division of Mines (CDM) has 95 percent of the data up to 1980. The 1981 and 1982 data are provided by the U.S. Bureau of Mines (USBM). The state totals from USBM are divided to the counties using the percent county ratio to total for the years 1976-80. At the time of the project, a preliminary estimate for 1985 became available from the USBM. Uranium data is not easily available. Some is listed in the C.D.M. data, and the remainder is obtained from historical information provided by W. Chenoweth. Unfortunately, the uranium data collection activity has been transferred from the DOE office in Grand Junction to Washington D.C.; therefore, it appears that data will not be available in the future. For some years, data on some or all metals in one or more counties has not been available and had to be estimated.

For most of the forecasting methods, historical data is needed. To carry out this project, we have collected historical data on the following items for the period of 1955 to 1982 (since no production data for 1983 was available):

1. Production data on a county by county basis for individual metals;
2. Mining employment data for each county on a mine by mine basis;
3. Metal prices;
4. Producer price index;
5. GNP deflator;
6. Mine and plant wage index; and
7. Miscellaneous indexes associated with the mining industry

There are several sources of production data for the state including the Colorado Division of Mines, the U.S. Bureau of Mines and the Department of Energy. There are two sources of employment data for mining in the state including the U.S. Mine Safety and Health Administration (MSHA) and the Colorado Division of Employment and Training. Metal prices are gathered from mining trade journals at the U.S. Bureau of Mines library at the Federal Center in Lakewood. Cost deflators are collected from copies of "Survey of Current Business" published by the Department of Commerce. For mining wages and the associated indexes of the mining industry, the quickest source is The Minerals Availability Field.

FORECAST

Assumptions

As noted earlier, trend analysis was the method chosen to carry out the forecast. Several assumptions are accepted by choosing this method of forecasting:

1. Metal value produced is related to general business cycles of the economy, it is a variable dependent on time.
2. The aggregate value of all metals is a better forecasting variable than the individual metal values.
3. Colorado's market share for the metals does not change over time.
4. There is no substitution for the metals over the forecast period.
5. There is no depletion of the metal resources in a county over the period of the forecast.

Trend analysis fits the data to a curve by minimizing the mean square error by using the least squares method. The problem is to find and use a curve that most closely approximates the data. Any curve can be used from linear to quadratic to a polynomial of some power to a sine wave function. Forecasts were carried out from linear to a fifth power polynomial equation. The linear trend forecast was chosen for this report because the data it produced was the only one that reflected reality. Statistical tests were not used in this decision (In spite of the absence of a complete body of statistical theory for forecasting in time series, the venture can still be made). Application of forecasting methods will depend upon careful formulation and the judgement of experts. (Chou page 534). This forecast was carried out using linear trends. First, the data were smoothed using a three year moving average. A trend line was fitted to the smoothed data. The trend line is the forecast for the years 1984 to 2003.

Results

The graphs of the forecast and tables of forecast vlaues are in Appendix B.

Equations.

The general form of the forecast equations used in the process is:

$$Y = A + BX$$

Y is the metal value in \$000's
A is the line intercept
B is the slope fo the line

The equation for the forecast line is $Y = 23797 + 14318 X$

Other variables forecasted

a. Employment

Employment data is available for individual mines in the state for the last six years for MHSA on a county by county basis. The county totals are summed to the state level. This data is used to establish a value for the number of man-years per \$000's produced. Appendix A contains a table showing the employment figures for the state for the six years that are available from 1978-1983. These employment numbers are divided by the value produced each year. The numbers which range from 0.010 to 0.014 averaged to 0.012 over the five years. This value is considered a productivity ratio for the state. That is, it took 0.012 man-years to produce \$1000 of metal value in the state. This number is considered a stable amount unless there is some technological or social change that makes mining manpower more or less productive. The ratio is multiplied times the projected value each year to arrive at a total number employed for the entire state.

b. Wages

Wages are forecasted using the mining wage index. The index is inflated at a five percent rate from 1983 to 2002. That hourly amount is multiplied by 2080 hours to arrive at a yearly figure and then multiplied times the employment amount to arrive at a total yearly wage paid.

c. Local purchases

This variable is forecasted as a percentage of the production amount. the percent is developed from a mine model. The model is built using the 'Cost Estimation Handbook' by Clement and published by the USBM. The model developed is for a large underground mine. This is used since 90 percent of the total value in Colorado is produced by the two molybdenum mines. The amount will vary with the size and type of mine but it is felt that, on the average, it would be suitable. The total production amount was multiplied by 12 percent and this gives the amount of local purchases for each year.

d. Production

Future production projections are based on the linear trend, projection of historical production. As such it is subject to the shortcomings discussed in the following pages.

FUTURE MODIFICATION USING FORECASTING ERRORS

There are some basic tenets of forecasting. They are:

1. Forecasts are very rarely correct;
2. Forecasts are more accurate for families of items; and
3. Forecasts are less accurate the farther they are extended into the future.

It is understood that the forecast will have errors in it. This is especially true of long range forecasts. The errors in this forecast will be caused by four conditions:

1. Technological changes;
2. Short-term depletion of a resource in a county or area;
3. Change in the economy; and
4. New mines discovered and brought into operation.

Any of these four conditions will cause a basic structural change between the data and the fitted trend line. These changes are called "turning points". They are points where the time series can no longer be forecasted by previous historical data. Quantitative forecasting methods such as the method used here can not predict these turning points. Hence, a method must be used to utilize the errors in the forecast after the turning point occurs and is recognized. Also, the modification method must be able to adjust for errors in the basic equation.

Modifications of forecast using errors

As stated above, errors will occur and must be used to modify the forecast for future years. One method that will show if errors are occurring is to plot the value

$$(\text{actual}/\text{forecast}) * 100 \text{ versus time}$$

This plot is shown in Figure 1. As shown any cluster of points that consistently fall above or below the 100 percent line indicates that the forecast contains an error. Any difference in the projected and the actual value is an error but errors must occur consistently on the plus or minus side of the actual for the projection to be in error. Therefore, deviations from the actual values can be expected. It takes more than one value to judge if the projection has a consistent error.

PLOTTING FORECASTING ERRORS

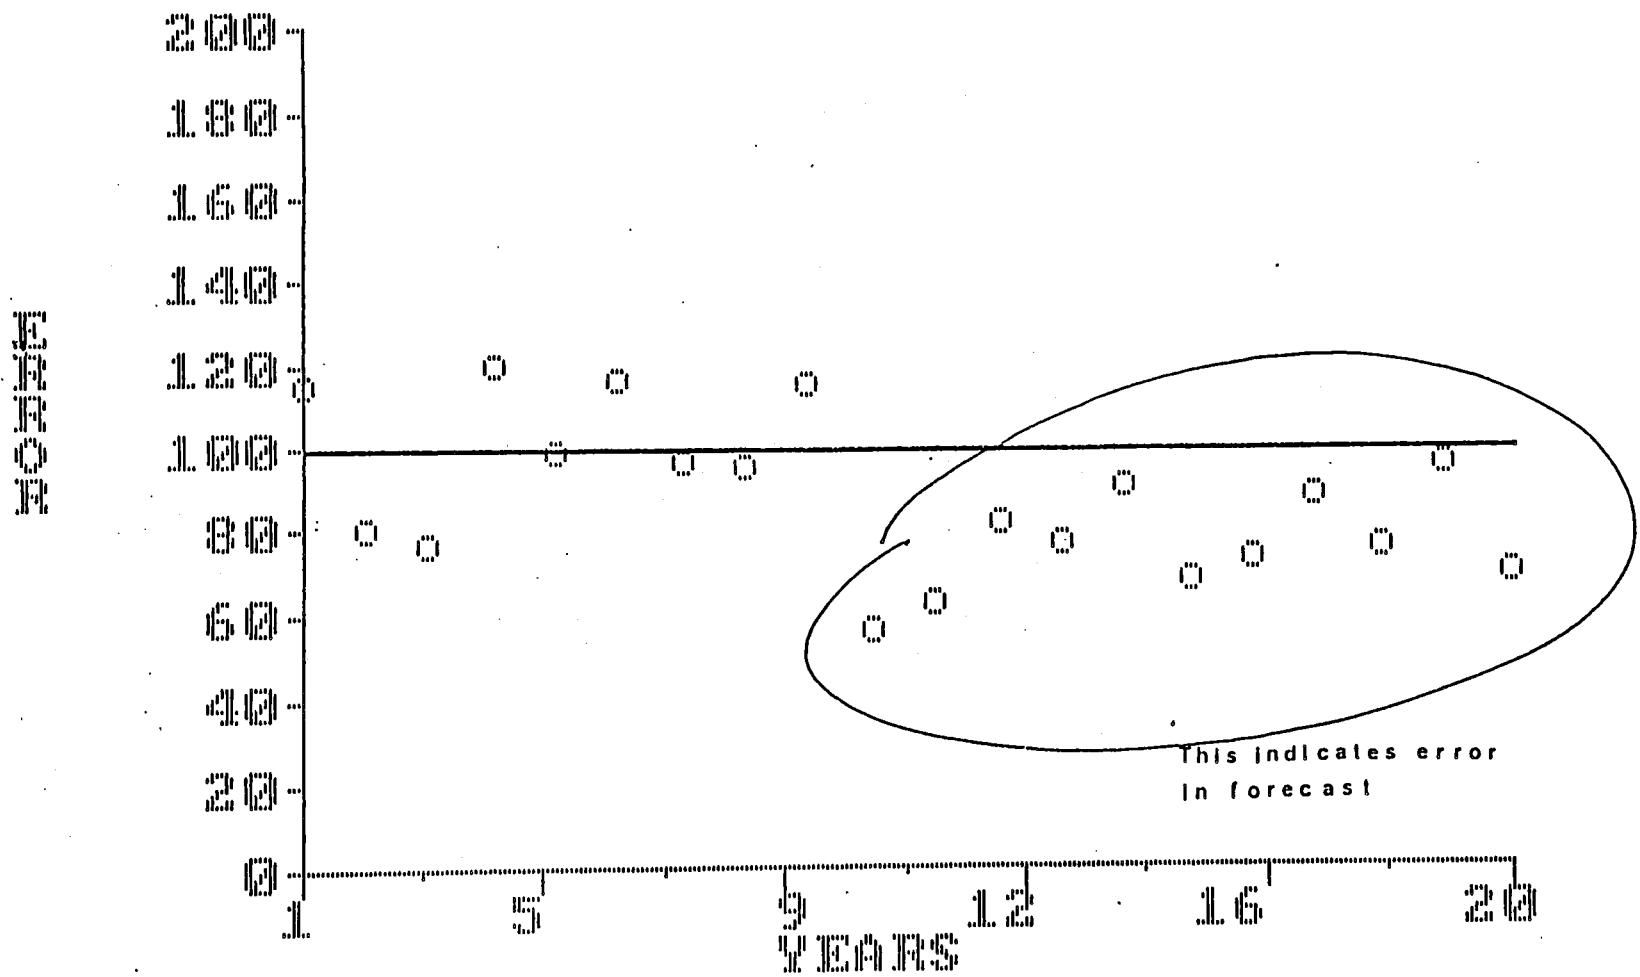

FIGURE 1

Modification of Production Forecast

The errors in the production forecast will occur because of:

Errors in the total forecast for the state, and
Errors in the ratios used to decompose the state total.

The line used for the forecast is:

$$Y = a + bX \quad a \text{ is the } Y \text{ intercept of the line when } X=0 \\ b \text{ is the slope of the line}$$

In this case,

$$Y = 23797 + 14318 X \quad \text{is the forecast equation for production.}$$

Modification of State forecast errors

The slope of the equation may need revising after several actual values have been obtained. This refers to the earlier statement of plotting the % error (+ or -) over time. The slope is the amount of increase of the production over the past year.

This refers to the earlier statement of plotting the percentage error (+ or -) over time. The slope is the amount of increase of the production over the past year.

Modification of County ratios errors

Errors in the county ratios are more difficult to deal with. The ratios are developed from the Colorado Division of Mines which no longer provides such interpretation and from confidential USBM data for the years 1976 to 1980. The publicly available data from the USBM is only available for the state as a whole, although there will be some county totals available, but not all. If any county has a new mine startup or a significant size change, a modification in the county ratio will be necessary. The size of the mine and the commodity would tell the analyst how much of a change to make in the county ratio. Sometimes trade journal, press releases, and company annual reports will tell how much the mine is producing either in total dollar value or quantity of metal. Also, a drastic change in one or more metal prices will be an indication that a county ratio may need change. This is especially true when only one price change and a county relies on that metal for production value.

Modification of Employment Forecast

Projected employment is dependent upon the production value. The employment forecast uses a constant number that reflects the employment in mining over the last five years. Employment is not included for the counties that produced uranium. To determine if the number is changing, the USBM total value for the year should be divided into the MSHA employment value for the year. The resulting ratio should be compared to the value used for the projection -- 0.012. If there is a substantial change, the forecast can be recomputed by multiplying the new ratio times the projected metal values.

Modification of Wage Forecast

The wage forecast is dependent upon the employment forecast. The projected 1983 wage index is multiplied by the employment to arrive at total wages paid. If the growth of wages is different from the five percent rate, the index should be recomputed. Also, the wages will have to be recomputed using the new estimate of mining wage growth.

Modification of Local Purchase Forecast

Local purchase projections are based on the production value. This estimate is more difficult to measure and validate. The value of 12 percent is chosen based on a model Colorado. From the 'Cost Estimation Handbook by Clement et al' published by the U.S. Bureau of Mines for a mine in Colorado. The model is developed to reflect that 90 percent of the value produced in Colorado is mined at two mines that are underground with an open pit associated with one of the mines. If this basic relationship changes, a new model will have to be developed.

CONCLUSION

Trend analysis is used to fit a linear line to metal production in Colorado. This produced a forecast which can be used to study the impact the mineral industry will have in Colorado in the future. The strengths of this forecast are its simplicity and the ease of modification as new data becomes available. It can easily be recomputed using a hand-held calculator or a personal computer with a spreadsheet application.

The forecast's weakness is its inability to forecast "turning points" which may significantly increase or decrease metal production in the state. Also, uranium, which was important to production values in the past, is not included.

A turning point has been reached for the mining industry in the past three years. Because of this, this forecast is an upper limit to value of metal produced in Colorado. The next two years will provide data that can be used to recompute the slope of the production line to bring it more into alignment with the new trend.

The two molybdenum mines in the state account for more than 80% of the metal value produced. This ties the value produced directly to molybdenum. I suggest using commercially available molybdenum forecasts to get a trend for the major portion of the metal produced in the state.

APPENDIX C
DATA SOURCES AND CONTACTS

Colorado Division of Mines
1313 Sherman Street
Denver, Colorado

Production Data

Data is available on a county by county basis from the late 1800's. Data is not complete, for any year part of all of the metal value for the county may be missing or may be aggregated into a single county amount. Data has not been collected after 1980. The definition of value for this data is 'amount produced in pounds, ounces, etc. times the average price for the metal that year, metal prices are as reported in trade journals, government reports or by the producer'.

U.S. Bureau of Mines
Karl Starch, Colorado Laison
Phone 234-3930
Bldg. 20
Federal Center
Lakewood, Colorado.

Production Data

This data is collected on a yearly basis and is available about May or June of each year. The data is on a mine by mine basis for each county and by major metal types. All single mine data is confidential and much of the county data is confidential as well. There is not uranium data in these numbers. The definition of value is 'production measurement by mine shipment, sales, or marketable production (including consumption by the producer)'.

Department of Energy
Nuclear and Alternate Fuels Division
Energy Information Administration
R. Gene Clark
Phone 202-252-6363
Washington, DC

Uranium Production Data

All data pertaining to production of uranium has been transferred from the Grand Junction office of DOE to Washington.

U.S. Bureau of Mines
Harold Benette
Minerals Availability Field Office
Phone 234-6266
Bldg
Federal Center
Lakewood, Colorado

Mining Industry Cost Indices

Cost indices and an entire set of cost curves are available from this office. The indices are updated quarterly for a monthly basis, and can be obtained over the phone. The cost curves are divided into three mixes for any part of an mining operation; they are:

1. Labor
2. Material and supplies
3. Equipment operation

The cost curves in the form of a computer program are available to the survey free of charge except for the cost of the tape they would be written on.

Mine Safety and Health Administration
Lenard Larson
Phone 234-5991
Lakewood, Colorado

Employment Numbers

Employment on a mine by mine basis for each county in the state is available from this agency. The data is collected and published quarterly. The final numbers for a year are not available until the spring of the following year. The data is free and is apparently public data. However, the data is only available for the last five years. Another five years beyond are available but on magnetic tape and requires some computer programming to get the data in a usable form.

Colorado Division of Employment and Training
Ken McNulty
1330 Fox Street
Denver, Colorado

Employment Data

Data on employment for mining in each county is available on a metal and nonmetal basis. The data is available for 1972 to the present, with 1974 and 1975 missing. It is updated on a quarterly basis. However, it is confidential for most counties and may not agree with the MSHA data.

U.S. Department of Commerce
Monthly
Survey of Current Business

Economic Indicators

This monthly journal contains indicators such as the GNP deflator, Wholesale price index, Consumer price index, and many more. These indecies are used to put historical data in constant dollars. This is the one source needed in order to carry out some of the more complex forecasting techniques.

William Chenowith
Consulting Geologist
Grand Junction, Colorado

Uranium Production Data

Production data for the years 1965 to 1980.
